INCIPIENT HYPOTHYROIDISM

A CLINICAL STUDY *

WILLIAM H. HIGGINS, M.D.
RICHMOND, VA.

The thyroid gland is the best understood member of the endocrine system, and, on account of its accessibility for extirpation experiments and other observations, its functions are fairly well established. The greater part of the literature on the thyroid deals with clinical entities resulting from an overactive gland, and it has been only in comparatively recent years that its underactive potentialities have been given serious consideration.

In 1874, Gull published his classic monograph, "On a Cretinoid State Supervening in the Adult Life of Women." Eleven years later, Schiff successfully transplanted the thyroid gland into the abdominal wall and initiated the treatment of thyroid insufficiency by feeding the desiccated glands.

In 1895, Magnus-Levy [1] demonstrated the ability of thyroid preparations to raise the rate of both oxygen and carbon dioxid exchange through the lungs, and in 1904, he [2] pointed out the principles of interrelationship between thyroid activity and basal metabolism.

It is now generally recognized that a reduction in the basal metabolism is the most constant single evidence of hypothyroidism. This statement is made with due respect to other glands which under certain conditions may lower the metabolism. The gonads may be included in this group. Rovinski [3] has shown that the fall of metabolism following castration largely disappeared if the thyroid was first removed, and he concluded that the lowered metabolism was due to a depression of the thyroid rather than directly to absence of the gonads. The influence exerted by the anterior lobe of the pituitary gland is similar to that of the gonads, and it is possible that it is accomplished also through the thyroid. The fourth organ that regulates metabolism is the suprarenal. Recent studies have shown that removal of the suprarenal glands from cats definitely lowered their rate of metabolism In a few cases of Addison's disease reported with metabolic studies, evidences of a reduced metabolism have been demonstrated.

Exhaustive studies on patients showing marked depression of their metabolic rates have been made from time to time by Plummer,[4] Means,[5] Sturgis,[6] and others,[7] all of whom found a close parallelism between physical signs and the percentage of metabolism.

This report deals with another group of cases in which the metabolic rates were sufficiently near the borderline to make the diagnosis of hypothyroidism doubtful, unless substantiated by other evidence. Twenty-three cases have been selected from the records at St. Elizabeth's Hospital,[8] whose metabolic readings ranged from —11 to —25. A probable diagnosis of incipient hypothyroidism was based on an analysis of the histories, physical findings and basal metabolisms, and was further strengthened by the beneficial effect following the administration of thyroid extract or thyroxin.

The object of the report is to emphasize certain so-called clinical syndromes which are not commonly found in the true myxedema types. In the majority of instances, symptoms referable to other pathologic conditions constituted the chief complaint.

RESULTS OF OBSERVATIONS

Sex.—The entire series consisted of female patients, as no metabolic studies were carried out on men.

Age.—The ages by decades were: from 1 to 10, one case; from 10 to 20, two cases; from 20 to 30, four cases; from 30 to 40, five cases; from 40 to 50, eight cases; from 50 to 60, two cases, and from 60 to 70, one case. It will be seen that more than half the patients were between the ages of 30 and 50, particularly at or following the menopause.

Level of Basal Metabolism.—The level of the basal metabolism in this series varied from —11 to —25 Low readings are generally associated with one or more of the unmistakable evidences of myxedema and very seldom occasion any difficulty in diagnosis. Sturgis, however, has reported the case of a physician who showed a metabolism of more than 20 per cent. below the normal and was entirely free of symptoms. In my experience, some patients with a low reading have shown fewer signs of a thyroid deficiency than others whose rate was considerably less markedly low.

From a diagnostic standpoint, the most important group for study is that in which the metabolism of the patients falls between —10 and —20. As a rule, evidences of a true myxedema are lacking, and there may be an actual hyperirritability. While the skin is often suggestive, the pulse may be accelerated, and loss of weight is not uncommon. In fact, the clinical picture of the mild hypo-active state may not differ very materially from the early hyperactive syndrome.

[8] All determinations of the basal metabolism were made with the Benedict Collins apparatus at St Elizabeth's Hospital, under conditions as nearly ideal as possible All tests were made in the early morning, after the patients had abstained from food or drink since the previous evening meal, and had rested in bed from one half to one hour preceding the determinations

Relation of Pulse Rate to Basal Metabolism.—Contrary to the usual conception of the hypothyroid patient, the pulse rate in our series was below 70 in only a few instances, and in some there was a definite increase above the normal rate. The pulse record was obtained during the metabolism test when complete relaxation was emphasized. At other times, there was often a definite tachycardia wholly out of keeping with the usual picture of an underactive gland. A probable explanation of this apparent deviation from the tendency to bradycardia is not difficult to surmise. While the pulse rate in true uncomplicated myxedema is relatively slow, the milder grades of thyroid deficiency are generally associated with other pathologic conditions which naturally may alter the pulse rate as well as the entire clinical picture. An accelerated pulse may therefore exist in spite of a definite hypothyroidism. In the more advanced type of myxedema, the degenerative changes in the heart muscle usually account for the presence of a rapid pulse. I was unable to establish any true relationship between the pulse pressure and metabolic readings in this series by the use of Read's[9] correlation coefficient.

Table 1.—*Incidence of Clinical Conditions Associated with Lowered Metabolism, in Order of Frequency*

Clinical Conditions:	Times
Colloid goiter	7
Ovarian disease or removal	4
Menopause	3
Obesity	3
Hysterectomy	2
Pituitary disease	1
Tetany	1
Cholelithiasis	1
Duodenal ulcer	1

Associated Clinical Conditions.—The chief clinical diseases that were associated with the group showing a lowered metabolism are listed in their order of frequency in Table 1.

Colloid goiter ranks first in the series, occurring in seven of the twenty-three cases. Although Plummer states that the basal metabolism in colloid goiter is usually between — 8 and — 15 per cent., one of this group had a basal reading of — 25.

Diseases of the generative organs and the menopause came next in frequency. In fact, the combined number of this type exceeded the incidence of goiter as an associated clinical condition. Experimental evidence seems to support the impression that castration tends to lower the metabolism. Aub,[10] for instance, favors this view on the assumption that the metabolism is lowered following the removal of the gonads, probably through depression of thyroid activity. Other studies, however, have failed to establish this relationship, although the subject has apparently not received the attention it deserves. The fact that many women show a tendency toward obesity after the menopause may be considered as evidence of a lowered metabolism, but there is no definite proof of such a decrease. The frequent onset of hypothyroidism at or during the menopause also suggests a relation between the ovaries and the thyroid gland.

The fact that more than one half of these patients were actually below their normal weight, according to the American actuarial standards, indicates that obesity is not necessarily a symptom of hypothyroidism. In Table 2, the relation of the age-weight to the metabolic readings is given. Only three cases can be credited with an excessive amount of adipose tissue. As pointed out by Means, obesity is not an indication of thyroid insufficiency, but may, in fact, show a moderate increase in the metabolic rate. It is not uncommon to find a lowered metabolism in an undernourished person who may actually gain weight under thyroid therapy.

Significant Signs and Symptoms.—In the well marked types of true myxedema, the signs and symptoms are generally so constant and typical that little variation is found. In the milder forms, however, a different syndrome presents itself which bears only a slight similarity to the fully developed types (Table 3). Dryness of the skin and dryness of the hair are common to both, but to a much milder degree in the incipient cases. In the present series, these signs were present thirteen and ten times, respectively. A premature wrinkling of the forehead, which may have some diagnostic bearing, was observed in a number of cases.

Nervousness of a local or general nature was one of the most frequent complaints. In some, it was a sensation of tingling in the extremities, or perhaps a sense of constriction about the head; in others, there were periods of depression, emotionalism or other evidences of a neurosis. As these clinical manifestations are so commonly indicative of a hyperactive gland, they are not generally sought for in the hypothyroid states.

Fourteen out of twenty-three histories emphasized vague unclassifiable pains as a prominent factor in the illness. This symptom was frequently referable to the abdomen, and was often the source of considerable annoyance in the diagnosis. It was generally inconstant, was neuralgic in type, and varied in intensity from day to day. The fact that the pain bore no definite relation to any particular organ or nerve distribution was its most characteristic feature.

12	48	67	160	4	..	—16							

Constipation and Headache.—These were complained of by thirteen and five, respectively, of the twenty-three patients. Although these symptoms are common in the true myxedemas, they probably are no more frequent in the incipient cases than they usually are in other conditions.

Localized Edema.—This was observed in seven patients, the lowest metabolism in this group being — 16. According to Plummer, edema generally decreases when the metabolic reading is about — 18 and increases as the depression becomes more marked. The swelling was of the myxedematous type in only one patient. In the remaining six, there was slight pitting of the ankles, a sense of tightness in the fingers, and a moderate fulness of the eyelids.

[10] Aub, J. C.: The Relation of the Internal Secretions to Metabolism, J. A. M. A. 79: 95 (July 8) 1922.

The absence of certain myxedematous signs was rather striking. In no instance was there any evidence of circulatory changes as shown by arteriosclerosis, vascular hypertension, cardiac abnormalities or renal complications. The patellar reflexes showed no demonstrable delayed response, as pointed out by Chaney,[11] in the more advanced types of hypothyroidism. Anemia was not a complicating factor, and there was no relative change in the differential count of the white cells.

Table 3.—*Major Signs and Symptoms Accompanying the Lowered Basal Metabolism, in Order of Their Frequency*

	Times
Dryness of skin	13
Dry or thin hair	10
Nervous (local and general)	17
Indefinite pains	14
[illegible]	13
[illegible]	7
[illegible]	5

GENERAL IMPRESSIONS

It is obvious that no definite conclusions can be drawn from this limited series; there are, however, certain impressions that may be worthy of consideration:

1. Incipient hypothyroidism is represented by a clinical syndrome largely distinctive from true myxedema.
2. In addition to a moderate degree of dryness of the hair and skin, neuroses, of various types, and vague unclassifiable pains constitute the most frequent complaints.
3. Obesity is relatively uncommon, and actual underweight is not infrequently found in the mild hypothyroid states.
4. Incipient hypothyroidism is more frequently found near the menopause and apparently bears some relation to the activity of the ovaries.

Prevention of Interstate Spread of Disease.—Under the quarantine act of Feb. 15, 1893, the Secretary of the Treasury is authorized to issue regulations for the prevention of the spread of contagious and infectious diseases from one state to another. These regulations may be enforced by the states, but the Public Health Service is authorized to cooperate in their enforcement, not only to prevent the spread of diseases, but to promote health. This is the means invariably taken. The wisdom of such a policy is shown by the substantial growth of state health agencies, the cordial spirit of cooperation that prevails, and the substantial advance made Examples of work of this character that may be mentioned are cooperative work in rural sanitation, and the examination of rodents to prevent plague and examination of water supplies used on vessels and trains engaged in interstate traffic There are great possibilities of extending such work, and it is along these lines that work of the Public Health Service will advance. The limitations of existing federal laws in this respect may be determined only by future judicial interpretation—Kerr, J. W.: *Pub Health Rep* **40**:1680 (Aug 14) 1925.

EXOPHTHALMIC GOITER (GRAVES' SYNDROME) AND INVOLUNTARY NERVOUS SYSTEM

XII. PATHOGENESIS *

HAROLD THOMAS HYMAN, M.D.
AND
LEO KESSEL, M.D.
NEW YORK

The abstract discussion of the pathogenesis of exophthalmic goiter may serve a threefold purpose—the interpretation of known data, the suggestion of avenues of approach for future study, and the development of a rational therapeutic regimen.

As we have previously shown,[1] the symptoms of exophthalmic goiter are identical with those which may be produced in any individual by effective doses of a sympathomimetic substance. We are still convinced that the participation of the involuntary nervous system is an important element in the evolution of exophthalmic goiter. Accordingly, a discussion of the pathogenesis of exophthalmic goiter necessitates a preliminary inquiry into the factors that may control the involuntary nervous system in health and disease.

The involuntary nervous system may produce the manifestations of exophthalmic goiter through the intervention of some unknown circulating sympathomimetic substance or substances. Thus far, attempts to demonstrate such a substance in effectual concentration in the circulating fluids have proved futile Again, the sympathomimetic symptoms may be produced by a loss of some restraining influence (parathyroid,[2] suprarenal cortex [3]) but this work is as yet too recent for adequate discussion. There is indicated an inquiry into the better established facts with regard to the involuntary nervous system.

The involuntary nervous system supplies with a dual and reciprocal innervation [4] practically all glandular tissue and smooth and cardiac muscle. Disturbances of the involuntary nervous system may, in consequence, assume an infinite variety of clinical manifestations—changes in the caliber of the bronchi and peripheral blood vessels, modifications of every conceivable type in the secretory and motor activity of the stomach, intestines and sweat glands, and every known alteration of rhythmicity, conductivity and irritability of heart muscle. Such changes may occur singly or in combinations of any variety. The occurrence of any such disturbance in function results in the production of symptoms through the entrance into consciousness of the activities of the involuntary nervous system. These symptoms lead the patient to the physician. The symptoms often point to one organ which, on careful examination, proves sound and free of demonstrable organic disease, and it is then that there arises the suspicion that the basis of the disturbed function is an alteration in the innervation These conditions are usually diagnosed as visceral "neuroses," but should be regarded, in our opinion, as local manifestations of widespread disturbances in the involuntary nervous system; i. e., autonomic imbalance.[5]

[4] Gaskell The Involuntary Nervous System, New York, Longmans, Green & Co, 1916

Autonomic imbalance is characterized by widespread and diverse clinical manifestations of instability of the involuntary nervous system, and by absence of demonstrable organic disease, and it runs a course punctuated by remissions and exacerbations. As a general rule, the patients suffer no severe inroads on their general health and form the large group of sufferers, the majority of whom are neither ill nor well, who wander from pillar to post and fall easy prey to the current charlatan. Of the myriad manifestations of autonomic imbalance, exophthalmic goiter is by far the most severe, the most complicated and the most debilitating. Any discussion of the pathogenesis of exophthalmic goiter presupposes an understanding of autonomic imbalance and its dependence, in turn, on disturbances of the involuntary nervous system.

We have not yet identified the factors that may regulate the tonicity of the involuntary nervous system in health, in emergency and in disease. To the endocrinologist, the involuntary nervous system is intimately concerned with the hormones; together they constitute a self-regulatory mechanism, a beneficent cycle in which the hormones regulate the activity of the involuntary nervous system; and the involuntary nervous system, in its turn, modifies the secretions of the glands. However, the very converse seems to be true, for the involuntary nervous system may function normally in the absence of the ductless glands,[6] and the ductless glands may continue to function after they have been deprived of their innervation. For the present, we may consider that the independence of the involuntary nervous system and the ductless glands has been established and that the inclusion in the realm of endocrinology of autonomic imbalance sets up a false hypothesis and suggests a useless therapeutic procedure.

The involuntary nervous system may be either stable or unstable. The instability may be either congenital or acquired, and it seems to increase in direct proportion to the advance of civilization. In each individual with autonomic imbalance, there is a characteristic manifestation of the instability which constitutes the "reaction picture." We do not know what determines the inheritance of the type of the "reaction picture," but, once established, this "reaction picture" is relatively fixed for that individual and may be evoked pharmacodynamically by the investigator. It is often quiescent (potential autonomic imbalance), but it may be activated in many ways. In the clinic, the most frequently observed activating agents are infection and psychic trauma. The sympathomimetic symptoms in early tuberculosis exemplify the activation by infection. More important, however, is the activation by psychic disturbances and emotional stress. Indeed, in almost every instance, irrespective of the original activating cause, the psychic factor eventually operates; for the visceral symptoms of the autonomic imbalance give rise to anxiety, and the "fear of illness" imposes on the "reaction picture" another activating agent (psychic trauma). A correct diagnosis may be, therefore, a potent psychotherapeutic agent. It may serve, prophylactically, to prevent the production of the cyclic reactivation of the symptoms, or it may serve to minimize the existing imbalance by removing the fear of organic disease. On the other hand, an incorrect diagnosis or a failure to recognize the mechanism of the production of the "reaction picture" may serve to perpetuate the symptoms. Such patients are often temporarily benefited, for example, by a Christian science practitioner, who denies the very existence of the symptom or by any therapeutist who will (like the charlatan), with the assurance of the ignorant, promise a cure. Many of the "cures" of organic disease announced by the various sects are, in truth, temporary remissions of an autonomic imbalance in which the "reaction picture" resembles the manifestations of an organic disease. An understanding of the pathogenesis of autonomic imbalance simplifies the therapeutic management; drug therapy plays a minor rôle and organotherapy none whatever.

Of the great number of patients with autonomic imbalance, only a small percentage develop exophthalmic goiter. Practically all patients with exophthalmic goiter *give a history of a diathesis; i. e., autonomic imbalance.* The transition from autonomic imbalance to exophthalmic goiter is characterized by the appearance of a metabolic change measured by an *elevation of the basal metabolic rate.*[7] Dependent on the elevation of the metabolic rate there develops a third group of symptoms (loss of weight, increased tachycardia, asthenia) which, in their turn, are due to the increased catabolism.

Such an increase in the energy metabolism may be produced by sympathomimetic influences, such as emotional shock or the amins of the epinephrin group or cocain. Were a sympathomimetic influence alone responsible for the metabolic change as well as the precedent imbalance, the management of exophthalmic goiter would be divisible into the care of the patient during the uncomplicated period of the imbalance (already indicated) and during the period of the metabolic upset. The latter period is, in our experience,[8] self-limited but may be curtailed through the use of iodids.[9] The tissues of the patient should be conserved (rest in bed) by proscribing any physical or psychic strain that might make extra energy demands and by furnishing exogenous fuel (high caloric diet).

However, the transition to exophthalmic goiter may involve the operation of an additional etiologic factor. The deficiency theories (parathyroid [2] and suprarenal cortex[3]) are not yet sufficiently developed to merit discussion. But the frequent hyperplasia of the thyroid gland has for many years directed attention to a possible thyrogenic origin for the disease. If the syndrome or any part of it, such as the metabolic increase, is due to a hyperthyroidism, the therapeutic policy outlined above is inadequate. However, there is no direct proof that the thyroid secretion is actually involved, for it is neither sympathomimetic [10] nor capable of sensitizing the involuntary nervous system.[11] It has a definite calorigenic capacity, however, and accordingly may be responsible for the transition from autonomic imbalance to exophthalmic goiter. In the absence of direct proof of a thyroid hypersecretion, many indirect claims have been made, the most important of which we shall now discuss.

COMMENT ON INDIRECT EVIDENCE

1. *Feeding enormous quantities of thyroid extract may occasionally produce an incomplete picture of exophthalmic goiter.* Such results, however, are not brought about by doses of the extract that fall within the secretory capacity of the gland; they are further open to the objection that the results are inconstant and may partially be explained by impurities necessarily present in tissue extracts. Furthermore, at least two major symptoms—exophthalmos and hyperplasia of the thyroid gland—cannot be elicited. We have frequently injected intravenously into human beings pure thyroxin in doses comparable to a marked increase in secretory capacity. Doses of 0.005 gm. thyroxin have not, in our experience, regularly caused any symptom other than an increase in the basal metabolic rate. In normal persons this is not accompanied by the syndrome of exophthalmic goiter; in patients with true exophthalmic goiter we have caused an elevation of the energy metabolism but no definite and regular exacerbation of the symptoms of the disease. On the contrary, in the grave complication of exophthalmic goiter known as the "crisis," the intravenous injection of thyroxin [12] seems to be a distinctly beneficial, if not life-saving, procedure.

2. *Hyperplasia of the thyroid gland occurs regularly in exophthalmic goiter, and this has been interpreted as indicative of a hypersecretory state.* The hyperplasia, however, is not accompanied by any measurable increase in the output of the thyroid secretion and is caused by [13] and associated with a diminished storage of the iodin-containing hormone. The hyperplasia is, therefore, a morphologic indication, not of a secretory state but of a decrease in the storage of the hormone. In pigs, hyperplasia may be associated with a fatal myxedema ("hairless pig malady"). This exemplifies [14] the simultaneous presence of thyroid hyperplasia and an almost total suppression of thyroid function. The hyperplasia, again, may be made to revert to the colloid state by the administration of any iodin-containing substance, including thyroxin. These facts render untenable the hypothesis that hyperplasia indicates hypersecretion. We regard the theories of dysthyroidism and toxic adenomas as rhetorical substitutes for the hyperplasia-hyperthyroidism hypothesis. Until it has been demonstrated that a pathologic qualitative change may occur in gland secretion, discussion of dysthyroidism is "tilting at a windmill." No reliable data have been advanced to show that adenomas can become toxic, and this theory is opposed by the work [15] that indicates that in the same thyroid gland the nontumor tissue functions more actively than the tumor tissue. Again, adenomas are so constantly found in the hyperplastic glands of endemic goiter [16] that any theory involving their toxicity must explain away their nontoxicity in the preponderating number of instances, to say nothing of their presence in the glands of cretins in goiter belts.

3. *Myxedema admittedly due to a hyposecretion of the thyroid gland is the alleged antithesis of exophthalmic goiter.* But the analogy is far from complete. Indeed, the two conditions have in common such characteristics as the lymphocytosis, and the changes in the sugar and nitrogen metabolism.[17] Furthermore, the two conditions may coexist, as is most often seen in patients, who, after subtotal thyroidectomy, have both the residual symptoms of exophthalmic goiter and a postoperative myxedema.

4. *The relief of the symptoms of exophthalmic goiter following subtotal thyroidectomy is the most potent and important clinical indication in favor of the participation of the thyroid in the development of exophthalmic goiter.* Surgical enthusiasts claim that the operative procedure is specific and curative. Previously they waxed equally enthusiastic with reference to vessel ligation, hemithyroidectomy and partial thyroidectomy. Now all seem agreed that the truly specific procedure is subtotal thyroidectomy. If this procedure were truly specific we should expect a rapid and complete detoxification, uninterrupted convalescence and a permanent eradication of the disease. The actual facts are difficult to elicit and more difficult to interpret; for, in the first place, the technical procedure is associated with at least two homely and vital therapeutic procedures—rest and psychotherapy, to say nothing of the preliminary detoxification with iodids. We have previously reported the efficacy of rest unassociated with purposeful psychotherapy. More than 80 per cent. of our patients were economically restored on an average of three months from the date of admission to the hospital, and today, on an average of forty-six months from the admission date, 54 per cent. of the whole group are still enjoying a relatively uninterrupted and spontaneous relief from their symptoms.[18] These figures represent a minimum, and we have purposely erred on the side of a conservative interpretation of results, so that in comparing the effects of specific therapy we might not deprive any patient of any potentially beneficial therapeutic procedure. As operative procedures include a preliminary period of rest during which the patient has preparatory operations or roentgen-ray therapy in addition to iodization, and a postoperative convalescence that includes weeks and often months of rest, before the effects of the specific therapeutic procedure can be evaluated, there must be subtracted such results as may be due to the nonspecific factor of rest.

A second procedure that is included in the operative results is psychotherapy. The importance of anxiety and fear in activating autonomic imbalance is equally great in the activation and perpetuation of the symptoms of exophthalmic gioter. Our patients almost without exception give a history of psychic trauma preceding or associated with the development of the symptoms of exophthalmic goiter. In addition, almost all have a true "goiterophobia" and regard the lump in the neck as the symbol of the disease. Eradication of this symbol is not only a surgical but a psychotherapeutic procedure; for to the patient, the removal of the symbol is synonymous with the eradication of the disease. The reassurance of the surgeon, who believes that his technical procedure is a specific measure, is an added factor in the establishment of this psychotherapeutic technic.

This factor, then, makes an interpretation of operative results all the more difficult. The results following operation, moreover, are not clear cut. Usually there is an immediate and definite fall in the basal metabolic rate, a slowing of the pulse rate and a diminution of many of the manifestations of the disease. These immediate operative results are due to the ablation of thyroid tissue. But this does not necessarily mean that the procedure is truly specific. The thyroid is but one of many factors that control energy metabolism. The fall in the basal metabolic rate following thyroidectomy is no more indicative of a specific effect on the etiologic agent than the antipyretic effect of the coal-tars in pneumonia is indicative of a specific effect of the drugs on the pneumococcus. It is reasonable that a fall in the basal metabolic rate should follow thyroidectomy in patients with exophthalmic goiter as well as in normal persons. From our observations, the fall is not specific. It is, in our opinion, nonspecific and may be considered as a grafting of an imperfectly antagonistic disease (myxedema) on another disease (exophthalmic goiter). The result is a cancellation of some of the manifestations of the preexistent disease. Again if the procedure were specific, there should be no residua and no recurrences.

In our experience, as in the experience of Judd[19] at the Mayo Clinic, residua—particularly exophthalmos, tremor, asthenia and palpitation—are commonly observed, and in addition we have seen true exacerbations of exophthalmic goiter in patients who have had a sufficient ablation of thyroid tissue to give them a basal metabolic rate that was subnormal. Very often, thyroidectomy is a helpful measure and succeeds in the alleviation of many of the symptoms of the disease. If these benefits could be accomplished at no risk to the patient, the end might justify the means. But the cost of thyroidectomy is great. There is frequently associated an alarming postoperative reaction—the "crisis"—and the general mortality is between 8 and 12 per cent. There are those who report an operative mortality for subtotal thyroidectomy in true exophthalmic goiter of less than 1 per cent.[20] Such exceptional surgeons are, indeed, to be commended for their skill; but in the hands of all others to whom we have spoken, the operative mortality is increased tenfold. When this risk is considered, in discussing the management of the individual patient; when, in discussing previous experiences with subtotal thyroidectomy, the late results with residua and exacerbations are brought up; when, from the good results, are subtracted such benefits as may have been derived from rest and psychotherapy, the establishment of a definite therapeutic policy furnishes a problem of nice discrimination.

This indirect evidence tending to demonstrate the thyrogenic factor in the etiology of exophthalmic goiter is not convincing. At best, the thyroid gland is but one of perhaps many etiologic agents. Despite a great deal of careful work, the administration of its products has not regularly produced the disease, nor has its removal regularly and completely cured the disease.

The pathogenesis of exophthalmic goiter is still open to question, and the therapeutic desideratum is still to be established. In our opinion, these problems will not be solved until we can determine the sympathomimetic influences that activate the quiescent autonomic imbalance and that may, under extraordinary circumstances, superimpose on the active autonomic imbalance the metabolic upset which determines the transition to exophthalmic goiter.

SUMMARY

The discussion of the pathogenesis of exophthalmic goiter is reopened because it is as yet an unfinished problem. In our opinion, exophthalmic goiter is a complicated disease, based on a disturbance in the involuntary nervous system, activated by many sympathomimetic factors of which infection and psychic trauma are examples, and superactivated, if you will, so that there is produced a metabolic upset whose origin is obscure—which may be thyrogenic, but which probably is not. An understanding of the steps in the development of the disease may serve to facilitate the study, to evolve new therapeutic procedures and to evaluate the old. The therapeutic desideratum is not yet approached, and should strike back, not at the cause of the metabolic upset, but at the sympathomimetic influences that are at the very basis of this and allied disorders.

145 East Fifty-Second Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. HIGGINS, AND HYMAN AND KESSEL

Dr. Lewellys F. Barker, Baltimore: I agree with Dr. Higgins that in thyreopenia the pulse may be accelerated. The patients complain of myalgia, of chronic constipation, and of dryness of the skin and hair. Some of them have ruddy cheeks and most of them are sensitive to cold. Drs. Hyman and Kessel have drawn our attention to the neural rather than to the glandular features of exophthalmic goiter—a return to the view held in pre-endocrine times. As I understand their conception, they combine the idea of a constitutional predisposition with that of additional factors that make the potential condition become an actuality. The evolution of the malady, they believe, occurs in two steps: (1) the transformation of a potential autonomic imbalance (by means of psychic insult, or of infection) into an actual imbalance, and (2) the acceleration of the basal metabolic rate, which they do not attempt to explain though they say it may not be of thyroid origin. This conception is interesting and should be carefully considered. I should like to ask Dr. Hyman what proportion of the cases had very high basal metabolic rates? The conception of hyperthyreosis as an explanation of exophthalmic goiter is not so well founded as we should like it to be. Hyperthyreosis, hypothyreosis and dysthyreosis are hypothetic constructions, which physicians have set up in the attempt to explain certain clinical syndromes; but whether such hypothetic constructions are valid is a different matter. It is the task of pathologic physiology to be critical of such hypothetic constructions, no matter how helpful they may be as working hypotheses. The marked increase in the basal rate in exophthalmic goiter and the fact that removal of part of the thyroid in bad cases is followed by marked amelioration of the symptoms make me hesitate to accept the view that disturbance of thyroid function is not important in the pathogenesis of exophthalmic goiter.

DR. I. H. MEANS, Boston: Dr. Higgins laid emphasis on a group of borderline cases with hypometabolism. I do not know the cause of these, but the important point to recognize is that some, if not all, of the symptoms can be relieved by thyroid. Thyroid should be used, however, with great care, and the metabolic rate should be followed. Another point that interested me was with regard to the pulse: I agree with Dr. Higgins that the pulse is an unreliable guide to metabolism. At the Massachusetts General Hospital, Dr. Field and Dr. Bock have been doing work on the minute volume of the blood in hyperthyroidism and hypothyroidism. In true myxedema they find that there is marked diminution of the minute volume of the heart, but that the stroke output is more reduced than the pulse. Emphasis has been laid by Dr. Higgins and by Dr. Barker on the type of indefinite pains seen in these cases. That interested me too, because I have seen it in my patients. There are intermittent pains resembling myalgia which disappear on thyroid medication. I have not the faintest idea of the actual cause of exophthalmic goiter. Dr. Hyman's hypothesis that there is a preexisting diathesis is an interesting one. Nevertheless, however much we speculate as to the cause, we must definitely decide about proper management of these cases. We must separate facts from theory in order to recognize the true indications for treatment. At present I believe that the thyroid, whatever the ultimate cause of the disease, is responsible through its overactivity for the more important symptoms. The effect on the circulation is partly that of simple elevation in metabolism which necessitates increase in circulation and overactivity on the part of the heart, and also perhaps in part that of nervous disturbances. The tachycardia in exophthalmic goiter is greater than one would expect on the basis of increased blood flow alone. This is important because tachycardia causes a wastage of cardiac effort; with rapid rates, total systole is increased and total diastole shortened. Dr. White has found that in a heart beating at 140, the total systole is 35 seconds a minute, and that with slower rate it may be 22 seconds. If that goes on for a long time, the effect is to deprive the heart muscle of its proper period of rest.

DR. SOLOMON SOLIS-COHEN, Philadelphia: As Dr. Barker has stated, the neurogenic theory of the origin of exophthalmic goiter is the older one, displaced largely through Kocher's work. Some observers, however, of whom I am one, have held to it throughout. We look on the goiter and the symptoms of dysthyroidism as incidents and epiphenomena. They may or may not be present. For that reason we prefer the term "Graves' syndrome" to indicate the fundamental disorder, on which the other features may or may not be grafted. The conception of autonomic imbalance, however, is much broader. It is that of an inborn, constitutional condition, out of which, according to the incidence of various exciting and determining causes, various syndromes may develop. Among the determining causes as well as the excitants are the vicissitudes of the patient's biologic history, both internal and environmental, and his native developmental tendencies. In 1893, I described, under the name of "vasomotor ataxia," a condition of instability of the neurocardiovascular apparatus through which its equilibrium becomes disturbed by causes of smaller degree than those necessary to affect the average individual; and by certain causes which do not affect the average individual at all. It was pointed out that this connection was the physiologic basis of many so-called idiosyncrasies, including hay-fever, asthma, angioneurotic edema, and other aberrant or exaggerated responses to excitants of various orders; and that it was frequently correlated with abnormal functioning of the thyroid gland.

Later, to express the idea more clearly, the term was amended to ataxia autonomica, with its English definition, autonomic imbalance, including the ideas of incoordination, instability, irregular function, etc. In the Osler Birthday volume the conception was still further enlarged to indicate a closer relationship with various endocrin disturbances.

These views have not met with general acceptance. I have therefore been very much gratified to hear the admirable paper of Dr. Hyman and his colleague, which in an entirely independent observation, traverses part of the same ground and affords, as far as it goes welcome confirmation. I have elsewhere expressed my objections to the terms used in apparent endeavor to escape the original one, by Eppinger and Hess, namely, "sympathicotonia and vagotonia," and by Morichau-Beauchant, namely, "angioneurotic diathesis"; and I am therefore still more pleased to find the present paper using, in apparent ignorance of my various discussions, that which I consider to be the inevitable term in a correct description of the conditions discussed—namely, autonomic imbalance.

DR. ELLIOTT P. JOSLIN, Boston: Care must be exercised in attributing a low metabolism to disturbance of the thyroid gland. In one group of diabetic patients there is a lowered metabolism. Prior to the work of Allen, diabetes showed a + 11 per cent., and after Allen's work started, the figures were — 11 per cent. Some of the patients had very low metabolism. I remember one which by either system, Du Bois' or Benedict's, showed from — 39 to — 44 per cent.; yet I do not think there was any hypothyroidism. These patients show dry skin, dry hair, constipation and nervousness, but they don't have headaches. As soon as they get more food their metabolism goes up. Therefore we should be very careful with this group of symptoms not to attribute it always to thyroid disturbance. In regard to goiter and mortality of operations for goiter, I am in a position to watch that, as each death in the Lahey clinic at the New England Deaconess Hospital comes under my supervision. I do not think that we should ask that the mortality in goiter should be lowered still further. It is low; it is as low as claimed by the clinic, and we turn over worse and worse cases all the time, even cases with very severe diabetes complicated with goiter. If these cases should present a high mortality, it is not against the surgeon. It is because we are taking advantage of his skill to stimulate him to do something still more wonderful.

DR. HENRY S. PLUMMER, Rochester, Minn.: It should be borne in mind that our concepts of thyroid function are largely working hypotheses which in writing and teaching are almost of necessity in sentences, paragraphs and even entire articles treated as established facts. It is impossible to avoid this and preserve a correlation of concepts except in long monographs or short articles of very limited scope. Dr. Barker's question of what was implied by the dynamic status of a cell calls for an involved statement. Briefly, it is the status that determines the quantum of energy transformed in a single excitation of a cell. Thyroxin, epinephrin, food and so forth are agents determining this status. I am one of the group who know but little regarding the etiology of exophthalmic goiter. Some of the theories that have been presented in the past may approach the truth, but to accept many of them at present necessitates a disregard of much contradictory evidence. That persons who through heredity and environment lack assurance and are prone to develop the phenomena of imbalance in the coordination of metabolic processes are also more prone to exophthalmic goiter has been recognized by most observers. On the other hand, no such evidence can be elicited in a study of many persons developing exophthalmic goiter. Furthermore, evidence of imbalance results from the physiologic status of the nervous system in exophthalmic goiter. Following the neurogenic hypothesis thus far, what I wish to insist on is the distinction of these phenomena of imbalance characteristic of man in general and the phenomena that characterize exophthalmic goiter. Our present hypothesis attributes the latter to the action of a toxin largely on the nervous system. This toxin may be an abnormal thyroid product or the product of the reactions of an abnormal thyroid product in the tissues of the body. Dr. Higgins presented a very interesting paper, one of a series that will in the near future flood literature. Regarding the majority of these cases with low basal metabolism, I wish to emphasize one point: Whether or not they are hypothyroid, we do not know. We do know that a high percentage of the cases that have in the past been diagnosed as neurasthenia, psychoneurosis or anorexia nervosa by neurologists, having much evidence of the autonomic imbalance described by Dr. Hyman, cannot be grouped with those cases which we know to be hypothyroid. We have hesitated to report this group as long as seemed practical as it opens up a vast field for the commercialists and the imaginative "endocrinologists."

Dr. William H. Higgins, Richmond, Va.: Dr. Joslin has emphasized an extremely important point in excluding contributory factors, such as diabetes, which could alter metabolism readings in the cases. Only by study of the patient as a whole can one arrive at definite conclusions. If there is the slightest doubt as to the result of the basal metabolism determination, it should be repeated over and over again. Those who are familiar with the technic of this test readily appreciate how easily errors can slip in. Thyroid extract is a potentially dangerous drug, and unless it is definitely indicated, as shown by a lowered metabolism, actual harm may follow its indiscriminate use. It is remarkable how the pulse rate varies from time to time. When comparative studies on the pulse are attempted, it is essential that the count be made under similar environments. A pulse rate at the end of the physical examination may very materially differ from the rate at the beginning of the examination and may show a wide variation from the record obtained at the end of the hour's rest.

Dr. H. T. Hyman, New York: Regarding those patients whose metabolism is above + 50 per cent., our average entrance metabolism is + 43 per cent., and we consequently see quite a few patients at a level of over + 50 per cent. I do not know whether the thyroid secretion is involved in these cases any more than I know its rôle in the milder cases. I have been confusing in my discussions of thyroidectomy. I was not discussing its therapeutic efficacy so much as its bearing on the pathogenesis of exophthalmic goiter. I do not deny that patients are often strikingly improved by thyroidectomy, though whether the results are better than in the "spontaneous course" series, we shall not be able to state for some time. Naturally the basal metabolism falls after thyroidectomy for exophthalmic goiter, just as it would fall after thyroidectomy in normals. But this fall does not prove that the elevation of the basal metabolism in exophthalmic goiter is necessarily thyroidal in origin, for it may be nonspecific, just as a fall of temperature following sponging in pneumonia is not a specific effect of the sponging on the pneumococcus. The mechanism of the therapeutic efficacy of iodids in exophthalmic goiter is interesting. It seems unlikely that they can diminish thyroid secretion. It may be that they supply a deficiency, for we think that at least some time in exophthalmic goiter there is a thyroid deficiency and we have reported what is apparently a life-saving therapeutic effect from the intravenous use of thyroxin in the febrile "crises" of exophthalmic goiter. I do not believe that the morphology of the gland throws any light on its function. I do not believe that adenomas can secrete an increased or altered and toxic secretion or that they are responsible for any clinical disturbance. Adenomas are frequently found in hyperplastic glands in normal individuals and tumor tissue in the thyroid cannot function as adequately as the nontumor tissue of the same gland. With regard to a therapeutic policy in exophthalmic goiter, we would be willing to waive objections to thyroidectomy on a basis of pathogenesis, if we could be persuaded that the procedure is innocuous and palliative. But we are not yet in a position to evaluate thyroidectomy in our own series and we are convinced that, while a small handful of men can and do operate for true exophthalmic goiter with a 1 per cent. operative risk, the general mortality rate is from 10 per cent. to 16 per cent. With regard to the work on the involuntary nervous system, the best clinical description of these disorders will be found in Trousseau. Our own work is not new. But we do wish to emphasize that there has not been demonstrated any relationship between the ductless glands and the involuntary nervous system. We regard them as independent.

HOT AIR COMFORT

ARE WE HYPERSENSITIVE TO TEMPERATURE AND HUMIDITY EFFECTS?

THOMAS HUBBARD, M.D.
TOLEDO, OHIO

Americans of a few generations ago lived in habitations and hostelries having temperatures of about 55 F., and, according to medical authority of 1820, this was the desired temperature even for hospitals, the sickroom and the nursery. "Not below 50 nor above 60" was the recommendation. We must infer that they considered this temperature comfortable and healthful. The comparison of 55 F. with the standard of today will bear some explanation. The fact is that the thermometer registered only the temperature of the air and did not give a reading of the actual comfort warmth, because in those days they depended on direct radiation, the luminous heat of the open fireplace. Radiant heat, like the sun's rays, does not primarily warm the air, but rather it warms the material objects of the room, including the occupants. The interception of the luminous rays was the chief source of heat, and there was only a secondary effect on the air, owing to indirect radiation from fireplace lining and fixtures and from the warmed material objects.

This was artificial heating applied in a natural way, an imitation of sun heating. Hence, a comparison of the past and present must take into consideration the fact that 55 degrees, as the standard, did not express the degree of comfort warmth of their habitations. Our forefathers did secure healthful comfort, even though they were in an atmosphere that registered only 55. Now we demand 15 degrees higher as the average comfort temperature of homes, schoolrooms, hospitals and hotels, having advanced, or perhaps one might say retrogressed, to about 70 as the average standard. Even 75 is not rare in our offices and habitations.

HEATING METHODS

Let us review the evolution of heating methods and, by reference to the law of physics, as applied to artificial heating, determine how and why we have drifted into our present unhygienic habit of being abnormally sensitive to temperature and humidity. Europeans—in fact, all peoples in the comparable zone and, in particular, our cousins in England and Canada—still have a comfort standard of about 60.

Fire was man's first friend in his primitive state; it made possible progressive evolution and brain development. Are we from 10 to 15 degrees more brainy, and are we hotter on the trail of truth than any other peoples, or are we physically declining in resistance to nature in her frigid moods?

Sensitiveness to temperature and moisture (what we call weather) variations is largely a matter of habit. It becomes a factor in resistance to infections, lowers vitality and retards convalescence. If we admit that we are 10 degrees more sensitive, is it not about the same as saying that we are correspondingly more subject to acute infections? Such a question must awaken a solicitiude in the minds of hygienists. Medical observers abroad assert that the American soldier in service was less tolerant of the cold in field service, in barracks and in hospitals, than was Tommy Atkins or the poilu. The reason is apparent. The man who is accustomed to a 60 degree living standard is less sensitive and is more resistant to low temperatures than one habituated to the 70 degree standard. The acute infections of our training camps can be partly ascribed to the upset of physiologic functions, as the result of hypersensitiveness to temperature changes.

We have drifted away from the standard of other peoples. American tourists abroad usually complain of the cold reception they get in travel, in museums and in hostelries, thereby advertising our inability to adapt ourselves to the foreign standard. An Englishman said that, when he first experienced American hospitality, he often felt like rushing outdoors to get a breath of fresh, cool air. A Canadian engineer, for some time a resident of the United States, confided that he loved this country and the people in the summertime, but that he and his wife were socially ostracized in the winter season, because they could not endure the hothouse reception of the American home. A New Zealander and his wife came to this country from a climate similar to that of California, intending to spend a month or two. They landed in New York in January, put up at a fine hotel, and hastily left in four days for Canada—to cool off. These Britishers were uncomfortable here, not merely because of our high temperature, but because of an unendurable combination of overheating and dryness of the air in our dwellings and hotels. These are samples of current criticisms on American heating standards.

A radical change in heating methods began with the Franklin open firebox in a cast iron stove; then came the sheet iron stove of the early part of last century. The hot air furnace and the hard coal baseburner came in about 1850, and soon afterward the steam and hot water radiators became popular. Invention and a superabundance of fuel were very seductive to a radical change in artificial heating, and we find the heat comfort standard steadily advancing. Even as late as 1860, it was still below 65 (62 was considered temperate), but it mounted to about 72 very soon after that time, and it has not dropped a degree, except during the war when the government pleaded for fuel conservation, and we endured 65 for a short time.

What is the essential feature of this radical change? It can be expressed tersely as the substitution of direct radiation, or radiant ray heating, by indirect radiation methods. The former gave a comfort warmth with a comparatively cool air content. The latter method depends on conveying heat by the hot air medium.

HEAT TRANSMISSION

This introduces the subject of the physics of heat transmission. Dry air is not a good comfort heat carrier, but moist air is. Saturated air (100 per cent. relative humidity) at 100 F. has about the same heat convection property ("effective temperature") as the same amount of dry air at 300 F. This comparison *of moist and dry air as heating mediums explains the* high American comfort standard. We are trying to get comfort warmth by using dry air as the medium of heat convection. The hothouse habit is a perfectly natural result.

A brief discussion of humidity may be necessary in order to explain what we mean by dry air. Water vapor is a natural constituent of atmospheric air, but there is no natural affinity between air and water vapor. The diffusion of water vapor in still air is dependent on vapor tension, and the meaning implied by "water hunger air" is a faulty conception. The problem of artificial humidification—the effort to keep the air of habitations healthfully moist—is the promotion and regulation of evaporation and the diffusion of the water vapor. In its application to habitations, it is not easy to solve. Air can carry water vapor, but it does not hunger for it; in still air, water vapor diffuses slowly. The whole process requires artificial aids; it is a real engineering problem.

Air has a definite capacity for holding water vapor, depending on its temperature. At 30 F., a cubic foot of air can hold only about 2 grains (0.13 gm.) of water vapor. At 72, a cubic foot of air can hold about 8 grains (0.5 gm.) of water vapor. In both instances, the saturation would be 100 per cent. relative humidity. The average relative humidity during the cold season in the temperate zone is high; that is, from 70 to 80 per cent. The temperature with which we are most concerned in this article is the low range, the freezing point or below. A 30 degree temperature and an 80 per cent. relative humidity means that each cubic foot of outside air carries less than 2 grains (0.13 gm.) of water vapor. When we convey this air into our habitations, either by the hot air furnace method or in the radiator heating systems by a natural leakage, and heat it up to 70, we have reduced the relative humidity to about 20 per cent. Obviously, we are trying to convey heat from stoves, furnaces or radiators through the medium of what may be called a very dry air, containing less than 2 grains (0.13 gm.) of water vapor per cubic foot (actually nearer 1½ grains [0.1 gm.] but allowance is made for body moisture, etc.). The lower the outside temperature the less is the natural water vapor (absolute humidity) content. At 20 degrees or below, there is about 1 grain (0.065 gm.) of water vapor per cubic foot brought into contact with the heater, and the relative humidity of this air, when warmed to 70, may be as low as 18 per cent. or even 15 per cent.

An indoor relative humidity of 20 per cent. has a dry-kiln effect; the walls and woodwork dry out, flowers wilt, exposed food becomes desiccated, complexions suffer, vigor is sapped by nervousness, efficiency is lowered, and even the furniture complains. Just as the piano is liable to be out of tune, so is domestic harmony. Hot air furnace heated houses will show a relative humidity as low as 15 per cent. on a very cold day. I have tested many office rooms in high buildings (steam heated, with pendent water evaporators) that gave a relative humidity of 17 per cent., and even as low as 14 per cent. An average of fourteen rooms gave 19 per cent. relative humidity. In high office buildings without artificial ventilation, each successive floor has a reduced humidity, as the structure is like an air-shaft, the natural movement of air being from below upward.

It is difficult to produce an evenly diffused humidity, when the very elements involved are contrary, and *when the average human being makes a demand almost* unpractical. Our forebears did not bother about this question of indoor humidity because they did not overheat the air. At their standard comfort temperature, say from 55 to 60, the relative humidity would not drop below about 35 per cent. and was probably higher even in the coldest weather because, to put it tersely, they lived in closer contact with the culinary department, and there was constant renewal of the water vapor content. Frosty window panes were more in evidence in those days.

We must recognize the fact that, in the heating of habitations, water vapor is the caloric comfort factor. In the humid summer season it becomes the discomfort factor, and likewise in winter when a cold damp atmosphere chills us even through our clothing.

Another interesting observation confirms the statement that we are depending on hot dry air for heat transmission. Dust, suspended in the air of a room, deposits on the surface that is cooler than the air, just as water vapor deposits on the cold window pane. The ceiling and wall above a radiator soon blacken with the dust accumulation; this is a characteristic of the hot air method of heating. Obviously the heat conveying quality of the air—i. e., the "effective temperature"—depends on the water vapor content. Consequently the habit of attempting to get comfort warmth by the medium of very dry air naturally results in an absurdly high comfort standard. It is unscientific, unhygienic and extravagant. This is a good example of a vicious circle; the higher the temperature, the lower is the relative humidity, and the lower the relative humidity, the more necessary it is to have a high so-called comfort temperature.

COMFORT

The word extravagance should be explained. The percentage of heat loss varies with the comparative temperature inside and outside, and is modified by wind pressure, window exposure, leakage and porosity of structure. As we raise the inside temperature from 60 to 70, there is a higher percentage of loss than in heating from 50 to 60. It will take almost as much coal to heat from 60 to 70, as from 20 up to 60. This comparison implies more or less imperfection in heating apparatus and faulty house construction—there are many factors involved not possible to estimate theoretically—and the only fact to be impressed is that a high comfort temperature should be classed as an extravagant luxury. The practical point is that a reduction of even 5 degrees means less extravagance. How can this be accomplished without discomfort? The answer is by conditioning the air used as a heating medium. We should have a proper water vapor content in our habitations and office rooms. This is the engineering problem. The first step is to create a popular demand and establish practical standards. Invention will respond to the demand. (The kind of occupation, the physical activities and the sedentary habits of a room's occupants have a bearing on the relation of humidity to comfort and efficiency; the rate of movement of the air content is also a factor. It seems best to limit this discussion to ordinary sedentariness in still air, such as obtains in homes and offices.)

In order to aid in establishing a standard, we may call attention to a yearly occurrence. In the fall of the year, the air of our houses has about the same relative humidity as that outside, owing to the free ventilation of the season. The contents of the house have absorbed moisture up to the normal. Cool days come, yet we are in no haste to light the furnace fire, an occasional open fire of an evening being sufficient. If we take a look at the thermometer, we find that there has been no complaint of discomfort even at 63 or 65 degrees. This means that the vapor content, probably near 50 per cent. relative humidity, warmed to 65 degrees, gives comfort, even though we have not donned cold weather clothing. That helps to fix a temperature standard, but it must be said that 50 per cent. relative humidity is rather too high for artificial humidification. The hygienic standard should be 65 degrees with from 35 per cent. to 40 per cent. relative humidity, for persons of normal health and vigor. Sixty-eight degrees of temperature with about 40 per cent. relative humidity should be the accepted maximum standard. This is a practical compromise, with a prospect of a progressively improved hygienic standard.

The term comfort zone, as used by heating engineers, merits explanation, because it is suggestive of the tendency of authorities on the subject to encourage a rather high temperature standard. For instance, 74 degrees and 20 per cent. relative humidity is reckoned as the comfort line, as also is the combination 70 degrees with 46 per cent. relative humidity. By contrast, we note that 68 degrees would require a 63 per cent. relative humidity to be at the same comfort line. It is impracticable to maintain a relative humidity above 40 per cent. in habitations, and, consequently, we tend to take the most convenient course; that is, to tolerate the standard of about 75 degrees with about 20 per cent. relative humidity.[1]

Hothouse coddling results in vagaries in wearing apparel. Fads cut loose and run to extremes. Just now, the lower extremities are on parade, and the fashions of the day exemplify the saying that clothing is for adornment and has little or no relation to comfort and utility. The high temperature standard tends to foster freak dressing, and one half-clad office employee dictates the temperature standard to others. The same is true of groups in public conveyances and in the home. The hypersensitive one compels all to tolerate his standard.

The thermometer is not popular nowadays. This is an age in which sensations alone can be depended on; and the worst of it is, that in a controversy, perhaps with her husband or the manager who relies on the mercury, it usually turns out that the complainant wins. A temperature of 70, with a very low relative humidity, may be actually chilly. So we stoke up the dry-kiln heater and roll along in the vicious circle with the comfort goal receding.

The skin and respiratory mucosa form the great, expansive sentinel area regulating the vasomotor system and heat loss. Evaporation from this area dissipates heat, and in a very dry atmosphere there may be a feeling of chill, even though the thermometer reads 70. The conventional clothing of civilization, combined with unhygienic heating, has literally doped the sentinel into sluggishness and has upset the physiologic function of the heat regulating mechanism. Sensations of discomfort follow and the subtitle of this article is confirmed: We are hypersensitive.

TYPES OF FURNACES

I have said that artificial humidification is an engineer's problem. For instance, in a hot air furnace system it is necessary to change the whole cubic air content from three to five times an hour, in order to convey the heat in very cold weather. To insure rapid changing, the air must be delivered from the furnace at from 120 to 150 degrees (some advertise 190). That is ventilation, surely, but it is a progressive desiccated process. Unless moisture is added, there is 15 to 20 per cent. relative humidity, and the more rapid the change, the lower the actual vapor content. In a nine-room house of about 20,000 cubic foot capacity, it would be necessary to vaporize 3 quarts of water an hour, more or less depending on the outside temperature, and on the inside temperature demanded. (If bedrooms and kitchen are not reckoned, the total is reduced.) As compared with 70 degrees, a standard of 65 would require about one-third less added water vapor to maintain a 35 to 40 per cent. relative humidity. The lower the standard temperature the less is the amount of water to be vaporized. But at least from five to eight gallons must be vaporated to maintain a fair humidity under the conditions mentioned—a nine-room house, hot air furnace and cold weather.

---

[1] The sling psychrometer, as used by U. S. Weather Bureau, is the most reliable humidometer. Stationary humidometers give misleading data, and textbooks and current literature give evidence of faulty readings of apparatus of precision. Even temperature-taking requires special precautions, such as properly placing the thermometer, and in comfort arguments the personal prejudice must be eliminated.

The term hot air furnace in this article is applied to that kind of a heating system which has only the direct cold air intake, without provision for rotating or recirculating the air of the house. When the outside temperature is very low, say below 20, the furnace must be very hot, the air must be delivered at the register superheated and, in order to convey sufficient heat, the air content of the rooms must be changed three or more times an hour. This is equivalent to heating three or more times the actual cubic air content of the house. Most of these hot air furnaces have a small water pocket in the side of the sheathing of the furnace, but the amount of water actually evaporated is negligible—it makes no impression on the relative humidity of the air of the house. The enormous amount of air in circulation makes humidifying unpractical. Such is the type in general use, and the term hot air is used as a selling attraction.

A heating system called the warm air furnace system is winning favor. The essentials of this system are a comparatively larger heating chamber and a perfected method of rotating (recirculating) the air, the return flow to the furnace coming from the cooler parts of the rooms or the hall. Fresh oxygen is supplied by natural ventilation. There is also leakage and a partly opened window situated just above the return flow register makes it practical to let in outside air without perceptible floor drafts. The working result is the warming of a large volume of air which enters the heating chamber not below 50 degrees and which is delivered at the register at a lower temperature than in the hot air system. Consequently the rate of air movement is slower, and it is practical so to condition the air that a fairly healthful humidity is assured. This is accomplished by an evaporating pan of considerable surface area, constructed as a part of the casting of the furnace. The water supply to this evaporating device can be regulated by the visible drop method. This special system is proving its claim to be called the warm air system. Recirculation gives air movement and even diffusion of water vapor, and the practical result is comfort at 68 degrees with 35 per cent. to 40 per cent. relative humidity.

The regulation of natural ventilation by windows or special devices will give a constant oxygen renewal, and as the inflow is influenced by the direction of the wind—a positive pressure on the windward and negative pressure on the leeward side—it is of advantage to have available ventilation inlets on at least two sides of the house.

Some furnace systems combine recirculation and air direct from the outside to the furnace heating chamber. This is more complicated to manage than ordinary natural ventilation, because of the above mentioned variation in air pressure, with varying winds.

Steam and hot water heating systems depend on leakage and natural ventilation for air renewal. The very names suggest humidity, but that is a delusion. A house heated by radiators can become just as dry as one heated by a hot air furnace system. It is difficult to vaporize water from a pan on the radiator, because the temperature is not high and diffusion is slow. One can make an impression on the average humidity by assiduous attention to many evaporating pans, but it is a real task—gallons to be evaporated daily—and, at best, only a partial success. Even a 30 per cent. relative humidity will help bring down the comfort temperature, and that is worth while. (The pendent water holders are quite useless, but there are some very effective evaporating pans on the market and also steam and water jet vaporizers more or less practical.)

We have considered three types of heating methods: the hot air furnace, the warm air furnace system and steam and hot water radiator heaters. Humidifying is difficult in all, but the warm air recirculation system combines a healthful humidity with fair ventilation. The hot air furnace and radiator systems, and likewise stoves, exemplify the statement that indirect radiation attempts to convey heat by the medium of very dry air. These types are the most popular heating systems, which have during the last half century made us victims of the hot air habit.

The various methods of humidifying the air, all with more or less complicated operating detail, emphasize the fact that this is a difficult problem, approach it as one will. It is one of the complexities of the artificial life, the outstanding feature being the high temperature standard which tends to make healthful humidification almost unpractical.

The reaction against frosty window panes is due to the notion that they always indicate bad air. This has been and even today in certain instances may be a correct inference, but we have gone to the other extreme in avoiding humidity. We should appreciate that with a properly conditioned air in the home a considerable frost deposit on the window is, in cold weather, one indication of a healthful atmosphere.

The open fireplace should not be neglected as a factor in home comfort. Its function is to supplement indirect radiation by direct luminous ray heating, in cold weather and between seasons. Properly utilized, the oldfashioned fireplace will help to bring comfort at a moderate temperature.

VENTILATION

Ventilation must be included in a hygienic survey of heating systems. I have left it for a closing comment, because, generally speaking, it is of comparatively less importance in the home life than is air conditioning. The cubic content per capita is usually ample to supply oxygen, and generous ventilation of bedrooms is the usual practice. A few years ago hygienists concentrated on carbon dioxid as the health destroyer, but now they understand that this exhalation gas should be considered merely as an index of air vitiation, and that it is deleterious chiefly because it displaces oxygen. The ventilation and humidification of the air of schoolrooms, hospitals, auditoriums, etc., presents special engineering and hygienic problems, the discussion of which would confuse the main issue. Air conditioning has already made great progress in certain commercial institutions, proving that it is practicable.

One of the striking results of a high comfort temperature, from 70 to 74, for instance, is that the occupants of a room become hypersensitive to drafts. The hotter the air content, the more shocking the effect of a cold air current sweeping along the floor from an opened window. Air from outside does help to restore invigorating oxygen, but it does not materially affect the moisture content, because the absolute humidity of cold air—the water vapor content—is very low and, when warmed up to 70, this volume of fresh air soon becomes about 20 per cent. or less relative humidity.

Ventilation should be practiced consistently, and this is one of the objects to be attained by conditioning the air of habitations to the proper humidity standard. The fact is that a healthful degree of humidity, and the moderate temperature that goes with it, mitigates the cold shock of a draft of outside air. The warmed water vapor, permeating even the clothing, prevents sudden chilling, and a healthful humidity becomes a factor in reducing the shock of cold, damp air on the mucosa of the respiratory tract. We would hear less about the beastly climate, if we were not made soft by the hothouse habit. The popular annual migration to the sunny southland is a confession of discomfort in office and home life; we exaggerate the vicissitudes of weather. This kind of complaining carries an admission of lowered vitality in physiologic resistance to cold.

SUMMARY

Americans are becoming progressively more sensitive to temperature and humidity.

The popular demand seems to be for higher radiation capacity in the home, in hotels and in public conveyances. (What a shock it would be to the heating trade if we accepted a 65 degree standard.)

Climatic conditions and sudden variations of weather are naturally very trying and we invite cold shock by hypersensitiveness.

Unhygienic heating combined with foolish estheticism in clothing (e. g., chiffon to furs) results in acute and chronic diseases of the upper and lower respiratory tract. Catarrhal affections, such as chronic sinusitis even in young children, are far more prevalent than should be tolerated by an enlightened, intelligent people. Medical progress in the study of causes of such diseases is one of the outstanding features of this age, but treatment and cure are handicapped when the unhygienic habit is in itself chronic.

The complexion is the color index of good blood and normal skin circulation. It is notorious that in America the natural color index is fading and the cosmetic index is correspondingly high. The skin, like the respiratory mucosa, is actually damaged by hot dry air (and likewise is the hair) and become more liable to chronic diseases.

Our present high temperature standard so lowers natural resistance to minor and major infections that restoration to normal health is retarded. The fresh air treatment of hospital surgical cases is testimonial to the healing virtue of tonic temperature and natural humidity in convalescence.

We must not delude ourselves into thinking that invention in the line of better conditioned warm air in our habitations is going to be given to us without rational effort on our part. Public sentiment must be educated to demand the reform, and the heating and ventilating business will surely respond. But even with perfected mechanical humidifying devices the desire to live hygienically can ge realized only by sustained, intelligent effort. We need a new conception of the deeper meaning of that good Anglo-Saxon word comfort.

ROENTGEN-RAY TREATMENT IN BRONCHIAL ASTHMA AND CHRONIC BRONCHITIS *

ISAAC GERBER, M.D.
PROVIDENCE, R. I.

This paper is not intended to be a presentation of anything absolutely new, but is rather a fresh emphasis on a field of radiation treatment that has been largely neglected in this country. The roentgen-ray treatment of bronchial asthma and chronic bronchitis has been developed chiefly in Germany. In fact, the available literature is almost entirely German. I know that some of the American radiologists have been using this treatment for years, but the value of the method has not yet penetrated the general literature.

Bronchial asthma is not, of course, a true disease entity; it has a wide variety of causes. The work, during the last decade, of Walker and his associates on the intrinsic specific causes of asthma has widened this field considerably. The present ideas with regard to anaphylaxis and protein sensitization have made the treatment of many of these cases much easier and much more hopeful. In addition, the recognition of extrinsic causes of asthma, such as nasal polypi, spurs, hypertrophied turbinates and chronic diseases of the abdomen, has been another help. In many of these cases, removal of these pathologic conditions has resulted in the entire disappearance of the asthma.

In spite of the valuable work in the fields mentioned, there are many patients who have undergone all types of sensitization tests, vaccine treatments, and removal of pathologic conditions in the upper respiratory tract, and yet their asthma has persisted, with perhaps an increasing frequency and severity of the paroxysms. It was just this type of unsatisfactory case that attracted my interest to the possibilities of roentgen-ray treatment.

One of the difficulties in the application of any novel therapeutic method is the fact that the exact mechanism of its action may not be entirely clear. That need not necessarily prevent us from employing the method. We are all familiar with the wonderful results that have been obtained by roentgen-ray treatment in various blood diseases, in diseases of the skin, in benign and malignant tumors, etc., yet in all these groups the exact mechanism of the beneficial effects of the rays has certainly not been worked out to a thoroughly satisfactory degree.

In the treatment of bronchial asthma with roentgen rays, two distinct methods have developed. Groedel and Lossen divide the methods into the direct and the indirect.

THE DIRECT METHOD

The direct method is the older one. This is the method of applying the rays directly to the thorax and its contained organs. The first cases date back to 1905, when Schilling accidentally discovered the beneficial effects of roentgen rays in asthma. He was making a fluoroscopic examination of the chest of an asthmatic patient for diagnostic purposes. This patient suffered from such severe paroxysms that he frequently had incontinence of urine and feces with his attacks. When Schilling saw the patient several days after this examination, the latter voluntarily told his physician that

---

* Read before the meeting on radiology in the Section on Miscellaneous Topics at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

for the first time in more than three years he had passed twenty-four hours without cough or expectoration. Naturally this excited Schilling's interest, and he started to treat other cases of bronchial asthma with roentgen rays. In most of the cases, he obtained an amelioration of the symptoms, a lessening in the amount of sputum and a lessening and even a disappearance of râles.

Since his time, a number of authors have contributed reports of similar cases. Steffan, Levy-Dorn, Epstein, Gottschalk, Immelmann, Bachem, Klewitz, Wetterer, Groedel and Lossen are the most prominent among the contributors to this field of therapy.

Wetterer also had some interesting experiences with accidental cures of asthma. He used the roentgen rays for the treatment of a case of acne of the chest and back, and also for a case of pruritus of the back and axillae, in which associated asthmatic attacks were found to have been cured.

Steffan utilized microscopic study of the sputum as a control in studying the effects of the treatment. He found not only a definite change in the amount and gross appearance of the sputum, but also a diminution and gradual disappearance of Charcot-Leyden crystals, of Curschmann's spirals, and of eosinophilic granules. Wetterer confirmed this and also found that the eosinophilia of the blood was reduced, following irradiation.

Schilling's last report was in 1910, at which time he had already collected sixty cases. He was able at that time to control the results in many of his earlier cases. He found that about one fourth of all the old patients had been definitely free from symptoms for more than two years. He was very enthusiastic about the method even in obstinate chronic cases, but felt that the chronic bronchitis of young people gave much more satisfactory results.

According to Schilling, the beneficial effects of the roentgen rays were due to the action on the ciliated epithelium in the walls of the bronchi, and particularly to the effect on the goblet cells which secrete the mucus. Gottschalk, on the other hand, believed that the action was primarily on the enlarged peribronchial and tracheobronchial lymph nodes. This is the idea that has pervaded the later literature, and seems to represent the general consensus of opinion. The presence of these enlarged glands is capable of causing irritation of the fibers of the vagus system. This irritation eventually produces the bronchial spasms that constitute the asthmatic paroxysm. Similar exciting irritations have been known to exist in such conditions as tumors and aneurysms. We have known for many years that roentgen rays are a valuable agent in producing a shrinkage of lymph nodes, enlarged from any cause. It is therefore reasonable to believe that in asthmatic cases, in which we can often roentgenographically demonstrate these enlarged nodes, the rays may have a similar shrinking action.

Holthusen has called attention to another possible explanation of the good results in the treatment of asthma. The desensitizing action of roentgen rays has long been known in connection with such conditions as pruritus, trigeminal neuralgia and sciatica. Here it is supposed that the analgesic action is due to a lowering of the threshold of sensibility of the nerve endings. In asthma, it is probable that a similar lowering of sensibility of the nerve endings of the vagus system might be produced following exposure to the rays.

Levy-Dorn and others have thought that, possibly, some of the results obtained in the relief of symptoms might be purely the results of suggestion. It is impossible, however, to explain on this basis the definite objective changes that result, particularly in the diminution in the amount and character of the sputum as well as in the lessening of the abnormal contained elements.

THE INDIRECT METHOD

The other general type of treatment is the indirect method, in which the rays are not applied to the thorax. This method, which has been utilized chiefly by Groedel and Lossen, also had an accidental basis. These authors were called on to treat a patient with leukemia, and they administered some roentgen-ray treatment to the spleen. The patient was a man, aged 56, who had been suffering from severe asthma for sixteen years. The physicians knew nothing about his asthma at the time, but continued to treat the spleen for leukemia. Nine months later the patient, whose leukemia had improved, told them that after the first application of the roentgen rays to the spleen, the asthmatic paroxysms had stopped, and there had been no return since. Following out this lead, they treated a number of other cases of asthma. Eventually they were able to report a series of forty-one cases of bronchial asthma in which the roentgen rays had been applied merely to the spleen, with no direct treatment of the thorax. Out of these patients, thirty gave excellent or good results as regards diminution or disappearance of the asthmatic attacks. In a number of cases, a single splenic exposure was sufficient to stop the asthma for weeks or months. More than three splenic treatments were not given in any case. Too frequent repetition was thought to be dangerous.

Groedel and Lossen also noticed that with the splenic exposure there was apt to be a general constitutional reaction of varying degree. In many instances, it was very severe and consisted of nausea, vomiting, headache, general prostration, possibly a rise in temperature, and sometimes diarrhea. Groedel noted that in the cases in which this reaction had been very severe, the eventual relief from the asthma was apt to be most striking and lasting. On careful study of the patients who recovered, he found that the great majority of them had had a very marked constitutional reaction. He concluded, therefore, that the severity of the secondary roentgen-ray reaction ran parallel with the amount of benefit to be derived from the splenic exposures. Incidentally, he felt that the constitutional reaction was due to a disturbance in the balance of the endocrine system. He did not observe any other bad results from the effect of the rays on the spleen. Some objectors thought that the treatment might produce splenitis or perisplenitis. No real evidence was brought out to show that this had ever been produced by the rays.

The explanation of the effect of splenic exposures is not very clear. Groedel was imbued with the idea of "Reizdosen," or stimulating doses, which Stephan had advocated. He believed that the small doses which reached the depths of the spleen stimulated it to the production of substances that acted like antibodies, and either modified the anaphylactic seizure or did not permit the production of the asthmatic spasms. This conception of stimulating doses is being gradually abandoned. In the present instance it seems more probable that the rays, even in small amounts, have some destructive action on the more embryonal cells of the splenic structure. The products of destruction probably initiate some sort of immunizing mechanism, acting possibly as antibodies, or perhaps stimulating the production of the latter. The recent work of Fried on the use of small doses of roentgen rays in inflammatory processes throws some light on the possible mechanism here.

COMBINATION OF DIRECT AND INDIRECT METHODS

In my own work on bronchial asthma, I have felt it desirable to use a combination of both the direct and the indirect methods. I expose the front and the back of the chest, and in addition give an exposure over the front of the spleen. In this way, I believe that the number of good results is apt to be greater than by the use of one method exclusively. We can get the good results from the chest treatment of those cases in which there is an obvious enlargement of the lymph nodes, and yet we will not miss the beneficial action in other types of cases in which it will be necessary to utilize the immunizing reactions.

I shall not attempt to present any statistical studies of my cases. The majority of the patients were treated in the roentgen-ray department of the Boston City Hospital. In a large municipal institution of this type, it is obviously impossible to follow up cases with any great satisfaction. In the future, however, I hope to be able to collect some figures regarding the permanence of the results and will submit them in a separate communication.

TECHNIC OF APPLICATION

The technic is simple. In the cases of true bronchial asthma I prefer to treat with the rays of short wavelength, using a voltage of either 170 or 200 kilovolts according to the apparatus available. The filter is 0.5 mm. of copper with 1 mm. of aluminum; the distance from target to skin is 50 cm. The dosage administered is from 10 to 15 per cent. of a skin erythema dose. I cover an area about 8 inches square over the front of the mediastinum, and a similar area over the back, at the same level. These two fields will include the main bronchial subdivisions. An area of the same size is treated with a similar dose over the front of the spleen. The three fields are treated on three separate days. In patients who are weakened by severe paroxysms, I prefer to have a day of rest after each exposure. This course of treatment is repeated if necessary in three or four weeks. Later treatment is guided by the condition of the patient and by the character of the constitutional reaction. Recently I have been cutting the dose down somewhat smaller and giving only from 8 to 10 per cent. of an erythema dose over each area. This is particularly advantageous with patients who are weak, and in whom we fear too great a secondary reaction.

I have noted the same severe general reactions that Groedel described, and also the parallelism between the severity of the reaction and the efficiency of the treatment. It seems to me that in the future we shall probably use smaller doses and perhaps avoid much of this reaction. By doing this, however, we may not get the prompt and effective response to treatment that we frequently obtain at present. This is one of the problems that remain to be worked out.

Clinically, some of the cases have presented very spectacular results.

One patient, J. G., aged 45, had had severe bronchial asthma for five years. He had undergone numerous courses of vaccine treatment with only temporary relief. For the last two years his attacks had been worse than before, and for one and one-half years he had never been more than several days without taking epinephrin. The spasms occurred chiefly at night, and he had acquired the habit of spending his nights sitting in a chair, dozing between attacks. Altogether, he had the worst case of asthma that I have ever encountered. I administered a course of treatment as described, with a day interval between the areas. There was a profound reaction, almost a collapse, lasting for a week. From the beginning of the prostration, however, the asthmatic attacks left him entirely. He did not have another attack for about four months, which was the longest interval without spasms for several years. At the beginning of a spell of cold weather he began to be uncomfortable. By giving smaller repeated doses I was able to control the paroxysms and make him fairly comfortable.

There is a wide variety of clinical response to the treatment. Some cases require only a single series of treatment, and may be symptom-free for many weeks or even months. It is best to be cautious and undertreat rather than overtreat. In a fair proportion of the cases there will be an initial increase in the frequency and severity of the spasms as well as an increase in the amount of sputum. For this reason I always like to treat one area at a time. If there is no increase in symptoms, I am ready to complete the series in regular order; otherwise, I prefer to wait another day. After the initial increase, in favorable cases the symptoms will begin to diminish and eventually disappear.

In addition to the cases of true bronchial asthma, the roentgen rays are of value in chronic bronchitis without any asthmatic symptoms. My own experience has been more with young children than with adults. The experience of the authors previously mentioned seems to agree generally that the treatment is more efficacious in younger persons. However, even in very long standing chronic cases some improvement may be produced. Of course, if permanent secondary changes have taken place in the lungs, the chances of relief from roentgen-ray treatment are not so hopeful. However, Schilling reports cases with definite bronchiectases in which he was able to measure the diminution in the daily output of sputum following the treatment. One case started with 75 c.c. daily, which diminished under roentgen-ray treatment to 5 c.c. within a few weeks. In my own practice, I have had two cases with bronchiectases of moderate extent. In both there was considerable relief from the treatment. In one of them, even though the rays were not applied to the spleen, there was a marked general reaction similar to that seen in the asthmatic patients.

In children, the treatment is especially applicable to the cases of slow disappearance of cough after pertussis. In many of these cases we are able roentgenographically to demonstrate enlargement of the tracheobronchial and mediastinal lymph nodes. Liebman of the Boston Children's Hospital, in a private communication to me, has described the results he obtained in a series of thirty such cases, practically all of which were cured by roentgen-ray treatment. I have also had cases of long standing cough in children lasting for some months, after an attack of influenza or grip. In these cases only a small amount of treatment is necessary. Sometimes three or four very tiny doses spread over an interval of two weeks will be sufficient to stop the cough. Liebman found that the roentgenographic examination of the chest after treatment did not show any very marked changes in the glandular conditions, although clinically the improvement was tremendous. This corresponds with my own experience in the few cases that I have been able to control by films after the treatment.

The technic with cases of chronic bronchitis is essentially the same as with asthma, except that the treatment is limited entirely to the anterior and posterior projections on the chest. I do not irradiate the spleen in these cases. The doses are slightly smaller than with asthma and are repeated every two weeks. In these cases, it is not necessary to use the short wave-lengths. If a spark-gap equivalent of 8 or 9 inches is available, we can use 3 or 4 mm. of aluminum and give 10 or 15 per cent. of the skin dose. With the very young children I give a much smaller dose, so that it can be repeated safely at intervals of twice a week.

SUMMARY

Many cases of true bronchial asthma do not respond to the removal of supposed extrinsic causes or to specific therapy, even though careful sensitization tests have been made. A large proportion of these patients may be markedly benefited by careful roentgen-ray treatment. In favorable cases there is a lessening and even a disappearance of the paroxysms and cough, a change in the amount and character of the sputum, and a diminution of the abnormal microscopic elements in the sputum.

Two types of roentgen-ray applications are used, one directed to the mediastinum and chest, and the other to the spleen. The mediastinal treatment probably has its effect through a shrinking action of the rays on the enlarged tracheobronchial and mediastinal lymph nodes, with subsequent diminution in the irritability of the local fibers of the vagus nerve. The mechanism of the effect through splenic exposure is not so clear, but may possibly be concerned with the release of antibodies which modify the anaphylactic seizure.

Chronic bronchitis without asthmatic attacks can also frequently be helped by application of roentgen rays to the mediastinum. The most favorable results are obtained in younger people, particularly in children who have persistent coughs after attacks of grip or pertussis. Cases of secondary bronchiectases that are not of surgical extent may be improved when other treatment is ineffective.

ABSTRACT OF DISCUSSION

Dr. Samuel Stern, New York: We have been doing this work for a great many years at the Mount Sinai Hospital in New York. We originally started by treating children who came to the clinic with asthma, and in whom roentgenogram showed that they had large glands at the hilum which we thought was possibly the cause of the asthma. After very few exposures, in the majority of these children, the asthmatic attacks decreased in intensity, and then finally after a comparatively short time, they disappeared altogether.

At this time, and for many years after that, we were using the low voltage treatment. We were filtering with 3 or 4 mm. of albumin, giving them half doses alternately from the front and the rear of the chest at weekly intervals. About a year and a half ago we took up the treatment of tuberculous adenitis with high voltage, with very small fractional doses, and we tried out the same technic in the treatment of these cases. The results have been most satisfactory. We give about one tenth of an erythema dose at weekly intervals. In the cases in which the asthma is due to an old unresolved pneumonia, our results have been even better. On examining them carefully, we find that usually there is some area in the chest which has not cleared up. This may be rather small, but a roentgenogram generally shows it, and a comparatively limited number of treatments bring on a resolution, with an improvement of the asthma. The splenic treatment spoken of by Dr. Gerber we have not tried yet. I am a little bit afraid to do much irradiating over a normal spleen. I do not mind treating the spleen when I feel that it is the seat of trouble, but I am a little bit reluctant to treat a normal spleen with a normal blood count. I do not know what doses these patients were getting. If they are getting only a very small fraction, such as a tenth or even less, I dare say it would be quite safe to treat them, and I am going to try it out. I should like to ask Dr. Gerber whether this series of cases that Dr. Groetel reports were all due to enlarged nodes in the chest, or whether there were other types of asthmatic conditions included. It is difficult to tell how the ray does its work in these cases. At one time, when we were treating with low voltage in comparatively large doses, we thought the action was direct on these nodes, making them shrink and disappear, though we found that often the asthma was improved before the nodes diminished much. But since that time, I think we have come to the conclusion that the rationale of the treatment is on a different basis. It is probably due to the more rapid stimulation of the antibodies.

Dr. Isaac Gerber, Providence, R. I.: I know that many Americans have been doing this work for many years, only unfortunately it has not spread over into general medicine. I have gone through the same attitude in regard to the character of the rays as Dr. Stern has. I have been doing practically all my treatment with the shorter wave lengths and copper filtration. I have been giving essentially the same dose as Dr. Stern, about 10 or 15 per cent., except that from now on I am inclined to give smaller and smaller doses. I am becoming convinced that the smaller doses will be much more efficient in starting these various mechanisms, and will be apt to produce far less harm. The same proposition applies to the spleen. With the dosages that I have been using, 10 per cent. or less on the spleen, with no repetition, or, perhaps, one or two repetitions at monthly intervals, I do not believe that any harm can result. With regard to the matter of unresolved pneumonia producing asthma, that is what I referred to, although I do not use the word pneumonia, in many of these cases of long standing cough after influenza or pertussis. Many of them are cases of bronchopneumonia that have not entirely resolved, and they can be demonstrated definitely on the roentgenograms. I feel that if this method is utilized more, we shall be doing an enormous amount of benefit for patients who are now shoved off in the outpatient departments of clinics and given potassium iodid and told that there is nothing that can be done for them. The asthma patients are constantly given increasing amounts of epinephrin, possibly morphin, and either of them to excess is not particularly good. I do not pretend that all these cases are going to be cured or ameliorated, but at least we have an agent that deserves more wide application, and one by which certainly a fair proportion of those hopeless cases can be helped.

Federal Government Public Health Activities.—The jurisdiction of the federal government in public health matters extends over foreign intercourse, interstate intercourse, federal territory and administrative affairs, including protection of the Indian tribes. As an example of these fields of activity and the methods of covering them, the District of Columbia may be cited as a strictly federal territory wherein local health matters are especially legislated for by Congress. It has likewise enacted laws to safeguard the life and health of the army and navy—highly important agencies in the administrative affairs of the government. Laws have likewise been enacted and agencies created to protect the Indians, the special wards of our government. In matters of health relating to international and interstate intercourse, the United States Public Health Service is the agency depended on. It operates through its own department—the treasury—or in cooperation with other departments having to do with factors other than health affecting international or interstate commerce.—Kerr, J. W.: *Pub. Health Rep.* **40:**1677 (Aug. 14) 1925.

PHYSICAL THERAPY *

MORRIS FISHBEIN, M.D.
Editor, The Journal of the American Medical Association
CHICAGO

No doubt the first agents of treatment used by man were those which could be had through simple adaptations of things natural. The application of heat and cold, rubbing and massage, and the use of water and of sunlight are as old as man himself. In the aphorisms of Hippocrates one reads of the uses of such methods; even at that time sound observers seem to have realized that these agents may act for good or for evil.

"Heat is suppurative," says one aphorism, "but not in all kinds of sores; but when it is, it furnishes the greatest test of their being free from danger. It softens the skin, makes it thin, removes pain, soothes rigor, convulsions and tetanus." But again, "Heat produces the following bad effects on those who use it frequently: enervation of the fleshy parts, impotence of the nerves, torpor of the understanding, hemorrhages, deliquia, and along with these, death." And in commenting on the latter aphorism, Galen and, still later, Celsus, said: "By 'heat' is meant 'hot water' or a 'hot fomentation.'"

Massage, too, was practiced in the earliest times: Anthropologists and ethnologists have described the practice as it exists among savage peoples today, and accounts are found in primitive medical texts. It is repeatedly referred to in the folklore of all nations, particularly in the tales of the Arabian Nights. Such massage included not only simple rubbing, but also pinching and kneading, later classified by French and Swedish investigators with technical terms.

The ancient Egyptians, the Greeks and the Romans were firm believers in the health-giving powers of the sun's rays. Indeed, Herodotus asserted that light must be regarded by the physician who knows his business as a means of repelling illness and as a subsequent aid to recovery. There were sun rooms in the homes of all the well-to-do Romans, not glassed-in sun-parlors facing north, as in our apartments today, but large central spaces, open to the sky and to the sun itself.

Humphris tells us that the first use of electricity in healing took place in the time of Tiberius, some twenty years after the death of Christ, when a physician named Scribonius Largus made use of the Raja torpedo-fish for rheumatism and for headaches. The electric ray-fish and the electric eel of Brazil are said to be able to convey a considerable shock. Scribonius Largus was, however, known chiefly for the scope of his writings, as his name no doubt indicates. His recommendation was based, apparently, wholly on empiricism. Much the same sort of reasoning assigned unusual virtues to mixtures of drugs of foul smell or of nauseous taste. The results commonly are the proof of the power of suggestion.

Of the birth of the roentgen ray and of the finer electric apparatus of our modern times, accurate descriptions are easily available. From the primitive observations of the past have arisen these remarkably complicated devices that have made necessary increased knowledge by the physician of physics and of chemistry, of physiology and of biology, and that call for a finer discrimination in their choice and in their application to disease than it has been necessary to accord to many of the drugs used in medicine.

SCIENCE VERSUS EMPIRICISM

The proper evaluation of evidence regarding the use of new methods in the treatment of disease is difficult. The patient is anxious to be well, the physician wants to see him cured or at least benefited as promptly as possible, and his friends and relatives constantly endeavor to encourage him, regardless of their actual belief as to the state of his illness. The result of this continuous positive suggestion is to lend to any method of treatment that may be employed a credence that is perhaps not its actual due. Few physicians—and, indeed, few scientists—can resist the hyperenthusiasm that is likely to follow a first successful result. The paths of the history of therapy are bestrewn with the wrecks of new cures that sailed forth as the last word in therapeutic achievement. Mental, manipulative, natural, mystical, spiritual and other cures have been brought forth by apostles of healing and vaunted as the secret for the solution of all the problems of healing that have confronted the physician since the earliest times. But when the apostle died, or when the primal faith that animated his followers disappeared, the cure went the way of the apostle.

Now physical therapy has been more subject to misunderstanding of its efficacy in varied conditions than has any other form used by the scientific physician. The potency of the placebo depends only on the mental suggestion and on the personality of the man who administers it. His contact with the patient is not direct. The contact of the chiropractor, the osteopath and the religious healer consists usually of the direct laying on of hands. Few physicians of experience fail to realize the importance of such immediate relationship to the patient. If more physicians took the trouble to make thorough examinations of their patients, never failing to examine the chest after the clothing had been completely removed from the upper part of the body and using auscultation, percussion and palpation, which are fundamental to physical diagnosis, there would be fewer failures and many more persons satisfied with the care of their physicians.

Without doubt, powerful suggestion is conveyed by the use of any intricate or striking mechanical method. The use of electricity, including the direct application of the current, the galvanic apparatus, pocket batteries and all the assorted forms of waves supplied through more intricate mechanisms, as well as the use of electricity to produce heat and light, is a striking therapeutic procedure. The late—but not too late—Albert Abrams well knew the value of intricate apparatus for impressing the patient and, even more, for impressing the uncritical physician. His first venture, spondylotherapy, carried with it a physically intensified suggestion; and those later Goldbergian evolvements, the oscilloclast and the biodynamometer, were impressive in their complexity even to some competent physicians.

Regardless of the fact that the underlying basis for many physical methods never has been thoroughly established and, indeed, is not even yet perfectly understood, the official organ of the American Electrotherapeutic Association only recently said: "The various irregular cults have also worked out in some instances methods that have sometimes succeeded where the rank and file of the medical profession have failed." The editorial referred to cites particularly the treatment of sacro-iliac strain, recommending, first, adjustment and, secondly, the application of electricity. On what basis does the editorial presume to say that displaced vertebrae once adjusted remain adjusted, unless held in

---

* Read before the American Electrotherapeutic Association, Drake Hotel, Chicago, Sept. 16, 1925.

place over long periods of time by methods of fixation? Who has proved that ligaments that are relaxed will resume their functions when the supposed luxations are properly replaced? Who has made the scientific studies, using the roentgen ray and all the other methods known to modern science, by which even an iota of truth can be attached to the claims of chiropractic and, indeed, to most of those of osteopathy? Granting that there is a modicum of truth in the claims of the latter cult, what scientific organization will be willing to admit that half-educated and incompetent men with no thorough understanding of the human body and its mechanisms should be privileged to apply any single form of therapy or diagnosis?

THE DANGERS OF SYSTEMS AND SPECIALTIES

If medicine is to be partitioned off into a series of specialties and cults practiced by men who have learned only one organ of the body or only one system of diagnosing and of treating disease, medicine as a science is bound to fail. No part of the human body can be detached and treated as separate from the organism as a whole. This danger threatens all the forms of physical therapy. It was no doubt enthusiasm for a single method that caused an editorial writer in the official organ of electrotherapy to say that "physical therapy will ultimately be recognized as of greater value than all other therapeutic methods." This concentration on an "all or nothing" policy in the treatment of disease must inevitably lead to preposterous and exaggerated claims, and ultimately to the detriment of scientific practice. Physicians have watched the inroads made on the practice of medicine as a single science. They have noted the attempts of optometrists to parcel off the eye as their particular field; of cosmeticians to assume the right to treat disorders of the skin and to request legislatures to grant them power to remove moles, warts, tumors and other excrescences; of chiropodists to assign to themselves the complete care of the feet; of chiropractors and osteopaths to make the field of manual manipulation their exclusive purview; and of some of the specialists within the ranks of medicine itself to assign all important functions to the teeth, to the lungs or to other organs of the body. The time has come to call a halt on geographic warfare within the human body, and to look on it as a "united states" that will be at least as firmly consolidated as the forty-eight individual constituents of our government.

If electrotherapy could point to a past that was free from the faults that have marred the progress of drug therapy since the earliest times, it would need no caution as to the future. But what has become of the hundreds of galvanic apparatus that struck amazement to the heart of trembling children led into physicians' offices some twenty-five years ago? Where are the little electric batteries that formerly occupied the showcases in the drugstores? Indeed, what has become of the claims for high voltage roentgen ray in the removal of deep seated malignancy? What a brief period it required for these claims, vaunted as the last word in the control of cancer, to resolve themselves into a method used only in apparently hopeless cases! The judgment may be premature, but it is based on scientific studies made in well recognized institutions for the study of human diseases.

PHYSICAL THERAPY PROMOTION

There was a time when the medical scientist, having completed his education in the field to which he wished to devote himself, opened his office, began teaching in a medical school with which he had affiliated himself, undertook the care of patients in legitimate hospitals, and left it to the recognition of the public to advance him to the limit of his merits. Today, modern high-powered business methods applied to the practice of medicine have pointed the way to the cults and to the hyperenthusiastic practitioner for promotion of his particular plans. All the forces of publicity are directed toward urging on the public the peculiar advantages that are claimed to accrue to single methods. The high priest of the peculiar system does not hesitate to instruct his followers in promotion of the system by all the arts and crafts—mostly the crafts—of salesmanship. There are physical therapists who believe that "high frequency" means the treatment of eighty patients a day. Again, organizations are established, not for study and investigation or for the promotion of knowledge in relation to the growth of any department of medical science, but primarily for the securing of public acclaim through the organization, rather than through the individual. The multiplicity of medical organizations is evidence of the fact that in some instances they are not established with investigation and study as their main objects. Consider in this connection the society called the Association for Medico-Physical Research. In its meeting, one program is devoted entirely to the claims of the now discredited Abrams method; another, to the exploitation of methods for the treatment of cancer, not one of which is established on any sort of a sound foundation; and still others to the promotion of systems of practice that should meet with nothing but the scorn of all who consider themselves honest and ethical practitioners of medicine. One finds here names of men known as faddists, who have discarded scientific rationality. One, without regard to the established facts of science, insists that a rice diet will prevent and cure cancer. Another promotes the treatment of cancer with a serum, regardless of the fact that carefully made investigations have revealed the failure of his method. There is G. E. Harter of the Defensive Diet League of America, who has collected a lot of miscellaneous aphorisms and peculiar concepts concerning food into a system and who has inveigled dentists of this country to his support with the idea that it is the duty of the dentists to establish the food habits of the nation. Among this miscellaneous crew of peculiar faddists appear the names of some physicians whose places on the program apparently represent an attempt to camouflage, with a sort of medical aristocracy, the fallacies that occupy the major portion of the program.

BASIS OF PHYSICAL THERAPY

The results of physical therapy seem to depend on many factors. Without doubt, rays of light have many and varying effects on the human body. Attempts have been made to separate them into effects of the light itself on the tissues and into chemical effects. Electricity has the power of acting through the heat that may be produced and, perhaps, through some effects produced by the current itself not yet determined; indeed, the mechanism is no better determined than is that of immunity in general. Electric stimulation no doubt has the power to act on nerves and on muscles, producing visible motive effects; and with such effects come mechanical changes. Is it not time that intensive study be applied in an analytic manner to determine to just what extent the benefits observed from the various electrotherapeutic measures are due to physical changes in the tissues, to mechanical changes in the tissues, to the power of suggestion, and, perhaps, to other factors of which we know nothing? Until some adequate basis on which the methods may rest is determined, no one can call such methods truly scientific. We have in physical therapy various methods of producing heat in the human body. There is the heat produced by friction; the heat produced by the external application of light, of hot water or of other heat-producing methods; and the heat produced within the body by diathermy, by the direct injection of heating material, or by the use of methods that will draw unusual quantities of blood to a certain point. In the evaluation of any form of physical therapy, who shall say to what extent the thermic factor alone is responsible and how far the other factors that have been mentioned have a part to play?

The numerous devices for effecting the production of heat, external or internal, for the body unquestionably vary in their potency and in their mechanism. How is the individual physician who knows little or nothing of the physical basis of electricity and, in fact, who knows little or nothing of any physics at all, except in the use of the term as it applies to castor oil and cascara, to have any actual knowledge of these so-called modalities? If the situation that confronted the American Medical Association before the establishment of the Council on Pharmacy and Chemistry was confusion, that of physical therapy resembles almost chaos. Drug products were compounds of chemical substances that might easily be separated into their individual ingredients. Scientific pharmacy had already made sufficient progress to warrant the statement that these ingredients would or would not do what was claimed for them. But when one is confronted with a large box beautifully trimmed with nickel plate and glass, the interior of which is a mass of wiring, spools, coils, gages, screws, nuts and whatnot, and is told that, properly applied, this apparatus will cure pneumonia, neuritis, lumbago, eczema, dysmenorrhea, falling of the uterus and falling of the palate, who is to tell one whether or not the machine will actually do all that is claimed for it? When the textbooks in the field of physical therapy tell the physician that the spine of the patient with locomotor ataxia may be restored to its pristine glory by running a few shocks up and down from the cervical region to the coccyx, is he to discard the prognosis that he has made in the past and to tell the friends and relatives of the victim of the wiles of Venus that his lapse from virtue is to have no further evil effects? What is the physician to do when he learns that most of the textbooks in this field are the products of men who are employed by concerns selling apparatus; when he is constantly besieged with lecture courses paid for by those who have something to sell; when his office is inundated with literature telling him that his financial future depends on the purchase of a vast amount of such machinery? Clearly, a house cleaning is badly needed in this particular field.

At the last annual session of the American Medical Association, held in Atlantic City, the House of Delegates, at the request of numerous members of the profession, voted the establishment of a Council on Physical Therapy, consisting of chemists, physicists, physiologists, pathologists and clinicians, who are to evaluate the actual worth of physiotherapeutic apparatus and methods, and to keep the medical public informed by regular statements of the actual truth or fallacy of such claims. At the meeting of the Board of Trustees held in Chicago early this month, a tentative list of membership for such a council was drawn up. It includes men who are leaders in the field of scientific medicine and in the specialties that have been mentioned, and representatives of the greatest universities and institutions for research in physics and physical therapy that exist in this country. Practically all of these men have volunteered to serve without a cent of compensation in order to give the medical profession unbiased and scientific statements concerning the physical therapy field. Their labors, as have been intimated, will be like the attempts of Hercules to clean the Augean stables. And the medical profession may confidently look forward to the time when the path between the vast accumulation of discarded refuse, jumbled wires, rusted hydrotherapeutic apparatus, peculiar tables and benches, worn-out electric bulbs, and other queer therapeutic apparatus, and the path leading by simple and clean methods to honest therapy will be clear. It is significant that the American Electrotherapeutic Association chose of its own accord to ask the American Medical Association for the appointment of such a council; that officers have taken steps to put it clearly on the side of scientific therapeutics, and that in the arrangement of its program they endeavored to secure material representing actual investigation rather than the exploitation of unknown devices or of therapeutic fallacies.

THE DIGESTIVE TRACT AND ENDOCRINE FUNCTION *

BRUCE C. LOCKWOOD, M.D.
DETROIT

The relation existing between various endocrine disorders and gastro-intestinal disturbances is often vaguely referred to in the literature. Unfortunately, much of the discussion deals with the hazy border-land of endocrinology, not frank endocrine disease, and with ill defined gastro-intestinal pathology. Before attributing gastro-intestinal disorders to hypothetic endocrine disturbance or to a certain endocrine constitution, we must determine whether there are typical or fairly uniform gastro-intestinal findings in typical, frank endocrine disease. If there are, we can assume that, at times, altered alimentary function may be due to slighter disorders in these glands.

This report is a clinical investigation based on a study of the gastro-intestinal tract of most of the frank endocrine cases, involving the thyroid, pituitary and suprarenal glands, which have come under my observation during the last few years.

THE THYROID

Hyperthyroidism.—The literature reveals contradictory opinions as to the effect of excessive thyroid secretion on the gastro-intestinal tract and the incidence of gastro-intestinal symptoms in hyperthyroidism.

Sajous [1] states that excessive thyroid secretion causes excessive metabolism in the gastro-intestinal mucous membrane and muscles, with increased secretion and motor activity, manifested by hyperchlorhydria, gastrosuccorrhea, frequent vomiting, diarrhea and serous light colored stools. One is led to believe that these are more or less constant findings. Barker[2] states that in exophthalmic goiter the gastric secretion, as a rule, is diminished, but that there are certain cases in which it is increased, and that vomiting and unmotive diarrhea are not uncommon. King[3] reports increased stomach and intestinal motility, with an achlorhydria in exophthalmic goiter.

---

* Read before the Section on Gastro-Enterology and Proctology at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

[1] Sajous, C. E. D., in Tice: Practice of Medicine, Hagerstown, Md. **13**: 237, 1924.

Wolpe[4] found achylia constant in all cases of pronounced types of exophthalmic goiter, but the hydrochloric acid unchanged in other types of hyperthyroidism.

Boenheim[5] states that after injections of thyroid extract the secretion of the stomach is raised. Leist[6] found that in eight cases of exophthalmic goiter, seven showed achlorhydria, and explains the finding on the basis of a subnormal protein content of the blood serum, rather than of a hormonic action.

Crotti[7] often found the stomach of exophthalmic goiter patients to be in a state of constant spasticity, when observed fluoroscopically.

Hardt[8] found that feeding dogs for two weeks with large doses of thyroid extract did not produce gastro-intestinal symptoms, but that the digestive acidity and secretion was slightly reduced. On the other hand, Rogers and his associates[9] found that on dogs with a Pawlow pouch the injection of extracts of the non-coagulable portion of the thyroid acted as a vigorous stimulant to gastric secretion.

Hammett and Tokuda[10] found that solutions of thyroxin in sodium hydroxid caused no more contraction of intestinal segments than did sodium hydroxid alone. Friedman[11] explains the various findings in hyperthyroidism on the basis of individual vagotonia and sympatheticotonia, while Boothby[12] believes that this grouping, as advanced by Eppenger and Hess, is not in accordance with the best experimental and clinical evidence.

The incidence of diarrhea in hyperthyroidism is variously given as from 11 to 75 per cent. of cases. Many of the data available are inaccurate, owing to the fact that only in recent years, since the more common use of the basal metabolism apparatus, have the early or milder cases been recognized.

Clinical Observation: Our study is based on a total of ninety cases of definite hyperthyroidism, a number of which were studied in association with Dr. Hugo A. Freund. These cases are divided into three groups, according to the types of goiter; namely, the formes frustes, the exophthalmic and the adenomatous types. The gastro-intestinal findings and their incidence are considered from the standpoint of the symptoms and the diagnosis.

Out of a total of ninety cases, with an average metabolic rate of + 35, twenty-four, or 36.6 per cent., showed some gastro-intestinal complaint. Nausea and vomiting, which are usually considered common complaints, were present in only three cases, or 3.3 per cent. of the total. Diarrhea, which is again considered common, was present in only four cases, or 4.4 per cent. of the total. These cases all occurred in the exophthalmic type, and constituted 16 per cent. of the cases in which such a diagnosis was made. Moderate or severe constipation was present in 16.6 per cent. and was about equally divided among the three types of goiter. Visible mucus in the stool occurred in eight cases. Jaundice occurred in one case of exophthalmic goiter, and was followed by immediate improvement in the hyperthyroidism.

Gastric analysis was done only in those cases presenting digestive symptoms. One achlorhydria was found in five formes frustes cases. It was found seven times in ten exophthalmic cases, and twice in nine adenomatous cases.

In Table 1 are tabulated the findings showing the incidence, symptoms and gastro-intestinal diagnosis in these ninety hyperthyroid cases.

Table 1.—*Incidence of Gastro-Intestinal Disease in Ninety Cases of Hyperthyroidism*

	Formes Frustes	Exophthalmic	Adenoma	Total No.	Total %
Number of cases studied	22	25	43	90	....
Average basal metabolic rate	+25	+48	+32	+35	....
Number having digestive symptoms	5	10	9	24	36.6
Symptoms					
Appetite poor	3	5	8	15	16.6
Nausea or vomiting	0	2	1	3	3.3
Gastric distress or pain after meals	1	1	1	3	....
Colonic distress or pain related to bowel movements	2	3	2	7	....
Constipation, moderate or severe	4	5	6	15	16.6
Diarrhea	0	4	0	4	4.4
Mucus in stool	2	4	2	8	8.8
Jaundice	1	0	0	1	....
Free hydrochloric acid absent	1	7	2	10	....
Free hydrochloric acid low	1	1	1	3	....
Free hydrochloric acid normal	3	2	6	11	....
Diagnosis					
Achylia gastrica	1	7	2	10	....
Peptic ulcer	1	0	1	2	....
Gallstones	0	0	1	1	....
Chronic intestinal stasis	4	6	5	15	....
Chronic appendicitis	1	0	1	2	....
Cecal stasis with spastic transverse colon	3	4	3	10	....
Catarrhal colitis	1	3	0	4	....
Mucous colitis	1	1	0	2	....

Comment: Nothing unusual is revealed by our study, except perhaps the low incidence of vomiting and diarrhea, which generally occurs only in the very severe cases of exophthalmic goiter. Achlorhydria occurred in ten of the twenty-four cases in which gastric analysis was done (41.6 per cent.), and was present more often in the severe cases. This suggests a tendency toward a diminution rather than an increase of gastric secretion in hyperthyroidism. Constipation, especially cecal stasis and irregular spastic haustration of the transverse colon, was rather common in the milder cases of the hyperplastic type. The incidence of other gastro-intestinal findings was perhaps not greater than among an equal number of persons not showing hyperthyroidism.

Hypothyroidism.—The literature is rather scanty concerning digestive tract study on cases of myxedema. This is probably due to the fact that myxedema patients seldom have abdominal complaints, except constipation. Sajous[1] states that in cretinism and myxedema the stomach does not appear to be the seat of disorder more frequently than in the cases of normal subjects. Sturgis[13] reports the gastric analysis in five cases of myxedema, of which three showed achylia, one a low acid and one normal acid. Katz[14] reports several cases

of hyperacidity in myxedema cured by thyroid extract, also some ulcer cases helped by thyroid administration.

Experimentally, Friedman[11] and Carlson and Jacobson[15] found gastroduodenal ulceration in about 75 per cent. of thyroidectomized dogs.

Clinical Observation: Ten cases of hypothyroidism have been studied. All showed a low basal metabolic rate, with varying degrees of myxedema, typical fat deposit distribution, and improvement under thyroid therapy.

The outstanding feature of the gastro-intestinal findings was the incidence of achlorhydria, which was present in 60 per cent. of these ten cases. Seven patients had constipation, and showed varying degrees of intestinal stasis with the roentgen ray. In one case the constipation was interrupted by an occasional outburst of diarrhea. Duodenal ulcer and chronic appendicitis were each diagnosed once.

Table 2 gives a summary of the findings in these ten cases of hypothyroidism.

THE PITUITARY

Beyer and Peter, in 1900, found that injections of pituitary extract at first gave a diminution, then shortly a marked increase, of rhythm and tone of the intestines. Bell, in 1909, called attention to the power possessed by pituitary gland extract to restore peristalsis to the paralytically distended bowel. Galán[16] found that hypophysial extract has an exciting action on the tonus and contraction of the stomach, both isolated and in situ. However, Ginsberg and Tumpowsky[17] found that 1 c.c. of pituitary extract caused an immediate inhibition of hunger contractions, lasting from one to two hours. Pancoast and Hopkins[15] observed the effect of pituitary extract on the gastro-intestinal tract in eleven patients. Pituitary extract was given intravenously, and a series of roentgenograms was taken during digestion. The results were somewhat variable, but as a rule there was a primary decrease, followed by an increase of the motility of the stomach, while the motility of the small and large intestine was generally unaffected.

Table 2.—*Gastro-Intestinal Tract Findings in Ten Cases of Hypothyroidism*

Patient	Basal Metabolic Rate	Gastro-Intestinal Symptoms	Gastric Acidity	Roentgen-Ray Findings
1	—13	Ulcer syndrome; constipation	F. 25 T. 35	Duodenal ulcer
2	—15	Constipation	F. 0 T. 37	Marked rectal and general colon stasis
3	—18	Moderate constipation; enteroptosis	F. 0 T. 18	Ptosis, cecum and transverse colon; cecal and rectal stasis
4	—18	None	F. 20 T. 40	Not done
5	—20	None	F. 0 T. 20	Not done
6	—28	Severe constipation; pain, right first quadrant	F. 0 T. 10	Cecal stasis; chronic appendicitis
7	—15	None	F. 35 T. 50	Not done
8	—18	Pain in lower abdomen; constipation; pelvic inflammatory disease	F. 15 T. 25	Cecal stasis; rectal stasis
9	—35	Constipation alternating with diarrhea; mucus in stool at intervals	F. 0 T. 12	Negative
10	—15	Moderate constipation	F. 0 T. 25	General colonic stasis

Englebach and Tierney[18] describe a general and an intestinal reaction following sufficiently large doses of pituitary extract. In treating cases of hypopituitarism the dose of pituitary extract is gradually increased until an intestinal reaction is produced. This consists of intestinal cramps coming from one to two minutes after the injection and followed shortly by a bowel movement.

Table 3.—*Findings in Ten Cases Presenting Evidence of Pituitary Gland Disease*

Case	Pituitary Diagnosis	Gastro-Intestinal Symptoms	Gastric Acidity	Roentgen-Ray Findings
1	Marked bilobar, insufficiency due to cystic tumor; necropsy	Moderate constipation	F. Neg. T. 10	Sella enlarged to size of walnut; gastro-intestinal examination not done
2	Moderate bilobar, insufficiency, aneoplastic	Constipation; gas distention and distress, relieved by an enema	F. Neg. T. 30	Sella small, gastro-intestinal examination negative, except spastic transverse colon
3	Moderate bilobar, insufficiency, aneoplastic	Nausea and occasional vomiting; constipation; colon bloating and distress	F. 47 T. 75	Sella small, spastic descending colon
4	Marked bilobar, insufficiency, aneoplastic	Tendency to mushy stools with occasional cramps in lower abdomen	F. Neg. T. 12	Sella very small, size of pea; spastic descending colon, ptosis transverse colon
5	Moderate bilobar, insufficiency, aneoplastic	None	F. 20 T. 30	Sella very small, gastro-intestinal examination negative
6	Moderate bilobar, insufficiency, aneoplastic	None	F. 23 T. 53	Sella small, gastro-intestinal examination not done
7	Diabetes insipidus	None	F. 15 T. 22	Sella normal, gastro-intestinal examination not done
8	Diabetes insipidus	None	F. 20 T. 50	Not done
9	Acromegaly	None	F. 30 T. 45	Not done
10	Acromegaly	None	F. 25 T. 45	Not done

Regarding the effect of pituitary extract on gastric secretion, Hess and Gundlack found no marked effect. Boenheim[5] observed an increased secretion, while Pal[19] and also Rogers and his associates[9] found a decrease.

The literature reveals little regarding the gastro-intestinal tract in pituitary disease. Englebach and Tierney report three cases of postadolescent bilobar pituitary insufficiency in which the presenting and chief complaint was severe lower abdominal pain, for which no local cause could be found. Blumgarten[20] also refers to cases presenting pituitary characteristics, especially the Frölich or Lorrain-Levy types, in which there are attacks of colicky abdominal pains, nausea and vomiting. He states that these attacks are always preceded by a frontal headache, often associated with blurred vision or dizziness, and often occur with menstruation.

Clinical Observation: Our observations cover six cases of postadolescent bilobar pituitary insufficiency, two cases of diabetes insipidus and two cases of acromegaly.

There were no consistent findings observed in the gastro-intestinal tract that could be attributed to the pituitary hormone. Achlorhydria was found in three of six hypopituitary cases, being present in the three showing the most marked hormonic signs. There was a tendency toward spastic manifestations of the colon, evidenced by distress and either constipation or mushy stools.. In two cases each of diabetes insipidus and acromegaly, no gastro-intestinal symptoms were present. The gastro-intestinal findings in these cases of pituitary disease are given in Table 3.

THE SUPRARENALS

Sibelli, in 1909, Finzi, in 1913, Mann, in 1915, and Friedman, in 1916, all found that in 95 per cent. of animals, hemorrhagic gastroduodenal ulceration followed the total removal of both suprarenals. Friedman also produced duodenal lesions in eleven of twelve dogs by administering epinephrin for two weeks. He explains the origin of ulcer on localized muscle and vascular spasm and relaxation, dependent on autonomic control by the thyroid and suprarenal. Mann, in a small series of cases of Addison's disease, witnessed at necropsy only one case of chronic ulcer.

Rogers and his associates found that injections of epinephrin and suprarenal nucleoprotein inhibit gastric secretion. Ginsberg and Tumpowski found that 1 c.c. of 1 : 10,000 epinephrin caused prompt and marked inhibition of hunger contractions for from one to two hours.

Loeper describes a number of cases of what he calls "suprarenal dyspepsia," a "fruste" suprarenal insufficiency, characterized by digestive atony and hypochlorhydria, cured by daily injections of epinephrin. On the other hand, Kaplan and Greef present three cases of what they term adrenopathic hyperchlorhydria, and they obtained symptomatic improvement and lowered gastric acidity by giving dried suprarenal by mouth.

It is generally stated that anorexia, nausea and vomiting, intestinal cramps and either constipation or diarrhea are common in Addison's disease; also that gastric acidity tends to become low or absent.

Clinical Observation: We have observed six cases of Addison's disease. All showed some gastro-intestinal manifestation, but no syndrome peculiar to the disease could be determined. Achlorhydria was present in half the cases and in those of longest duration. Ulcer of the stomach was suspected in one case on account of the history of a hemorrhage, but no lesion could be demonstrated by roentgen ray. Nausea and vomiting were present only once, and then they were associated with dizzy spells and were probably of central origin. Severe constipation was found in half the cases, and diarrhea in one third of the six cases. Anorexia was present to some degree in all cases. In Table 4 is a summary of our findings.

Table 4.—*Findings in Six Cases of Addison's Disease*

Patient	Blood Pressure Systolic	 Diastolic	General Symptoms	Gastro-Intestinal Symptoms	Gastric Acidity	Roentgen-Ray Findings
1	100	65	Duration, 6 months; weakness, loss of weight, pigmentation of skin, headache and dizzy spells	Constipation for 10 years; spells of nausea and vomiting, with dizziness	F. 24 T. 65	Not done
2	94	66	Duration, 1 year; weakness; loss of weight, nervousness; pigmentation	Diarrhea, 4 months; intestinal stasis; colonic distress	F. 58 T. 82	Three cycle peristalsis and spastic pyloris; pericecal disease
3	85	60	Duration, 3 years; weakness, pigmentation, tuberculosis of lungs moderately advanced	Constipation; hard scybalous stools; pain in epigastrum relieved by bowel movements	F. 0 T. 21	Cecal stasis; spastic irregularity; haustration transverse and descending colon
4	86	65	Duration, 3 years; weakness, pigmentation, cold extremities, dyspnea	Anorexia, constipation	F. 0 T. 12	Not done
5	105	75	Duration, 1 year; weakness, pigmentation, dizzy spells	Severe gastric hemorrhage 9 months before; no symptoms	F. 18 T. 34	Negative
6	95	70	Duration, 4 years; marked pigmentation, loss of weight, dizzy spells, weakness	Diarrhea spells for 1 year; colonic distress and gas; mucus in stools; no pus	F. 0 T. 25	Spastic descending colon

Regarding the lesser or "fruste" forms of suprarenal insufficiency, I have not recognized any cases in which gastro-intestinal manifestations could be attributed to such a cause with any degree of certainty.

COMMENT

The gastro-intestinal tract may be considered as a muscular tube endowed with a normal muscular tone, rhythmicity and irritability. It is essentially an automatic organ like the heart. Its stimuli to movement and secretion arise within itself, but these movements and secretions are also regulated by the action of the extrinsic nerve fibers, so as to adopt them to varying conditions.

The innervation of the digestive tract consists of a system of nerves, ganglions and end-organs, about which very little is definitely known. It is a complicated automatic system, sensitively affected by emotions, reflexes, general states of the body, such as toxemias, and infections, as well as by the daily changes of body functions that take place in health. This system is composed of the sympathetic and the vagus ramifications, together known as the autonomic system. The vagus and the sympathetic are assumed to have opposite effects on the gastro-intestinal tract, and to balance normally each other.

The condition of imbalance on the part of these two portions of the autonomic system leads to gastro-intestinal dysfunction. In recent years considerable interest has been manifested in explaining gastro-intestinal pathology and pathologic physiology as being due to autonomic imbalance, which in turn is due to various states of endocrine gland hypersecretion and hyposecretion. That such an explanation may be and often is the correct one is not questioned, yet it seems reasonable to expect more constant gastro-intestinal disturbances in marked and manifest endocrine disorders than is the case.

It must not be forgotten that gastro-intestinal function is influenced by other factors as well as endocrine changes. Indeed, Schnabel[21] found a very small percentage of 350 consecutive gastro-intestinal cases showing endocrine disturbances. Further, it is true that a person of a certain endocrine type, or even having an endocrine disorder, may have gastro-intestinal and other disturbances, dependent on etiologic factors that are not endocrine, and such should be considered in the diagnosis and treatment.

---

[21] Schnabel, T. G.: Pennsylvania M. J. **24**: 229 (Jan.) 1921.

The incidence of gastro-intestinal disturbance in our ases, as previously cited, was less than often considred, and in general occurred in the endocrine cases howing the most marked general bodily changes.

CONCLUSIONS

1. The gastro-intestinal tract shares with the rest of he organs of the body in the secondary effects resulting rom disturbances in the functions of the endocrine glands, but not to the extent that is often considered. The exact mechanism is not definitely known, but it is probably through both the medium of the autonomic nervous system and changes in the general bodily nutrition.
2. Slight endocrine disorders seldom produce gastrontestinal disturbances.
3. In general, the stomach acidity tends to be lowered by hyposecretion of the thyroid, pituitary and uprarenals.
4. Hyperthyroidism also tends to reduce gastric acidity, achlorhydria being a frequent finding in exophthalmic goiter cases presenting gastro-intestinal symptoms.
5. Peptic ulcer is not common in manifest endocrine disease, having been noted only four times in 126 cases.
6. In endocrine cases in which there is intestinal disorder, the most common lesion is spastic rather than atonic.
7. In gastro-intestinal cases, all other etiologic factors should be excluded before incriminating the endocrine glands.

ABSTRACT OF DISCUSSION

Dr. William Engelbach, St. Louis: The incidence of gastro-intestinal symptoms in endocrines is difficult to determine. It depends on the physician interpreting these cases. The etiology of many of these endocrines is in dispute; various schools have made different groupings. The stage of the disorder and length of time a patient is observed would give a different percentage. A gastro-enterologist might for a few days or months find no endocrine symptoms, yet later symptoms may occur.

I would take issue with Dr. Lockwood regarding his statement that hyperacidity is a constant finding in myxedema. The gastro-intestinal effects in these cases are undoubtedly due to the disturbance of the autonomic nervous system, which is so definitely affected by the internal secretions. For this reason, there is probability that the motility of the gastro-intestinal tract is affected more than its secretions, although these secretions must be decidedly modified at various stages of incretory imbalance. It has been our experience that hyperthyroid individuals most commonly present gastro-intestinal symptoms. Next, we have found that the hypogonadisms, in other words, the castrates, persons with status lymphaticus, and eunuchoids, are most frequently troubled by gastro-intestinal symptoms. The bilobar pituitary disorders, such as Froelich's disease in the postadolescent age, also frequently have very marked gastro-intestinal disturbances. We have not found gastro-intestinal symptoms so frequently present in acromegaly and gigantism, except in those cases due to pituitary neoplasm in which these symptoms are due to intracranial pressure. Our studies made on more than 200 cases, including early and late castrates, eunuchoids, and patients with other primary and secondary gonadal insufficiencies, have revealed that disorder of the generative system has been a most prevalent cause for symptoms referable to the gastro-intestinal system.

In 1918, I reported a case which had been under our observation for five years for persistent vomiting. This woman had had her appendix removed at the onset of the disease, and later an exploratory laparotomy was done without finding the cause for her prolonged vomiting which had produced a very severe emaciation. After the exploratory operation, at which time no intra-abdominal condition was found to account for the nausea and vomiting, she was placed on extract of corpus luteum, which had been placed on the market a short time previously. Following this treatment, she was relieved of all her symptoms except the complete amenorrhea, which had been present for one year previous to her last operation. Since this time, she has been under observation more or less constantly and various other preparations have been given her for recurrences of the anorexia, nausea, vomiting and loss of weight, which usually occur in the order named. No medication other than ovarian preparation given hypodermically has relieved her symptoms.

Dr. A. J. Carlson, Chicago: In the work on dogs referred to by Dr. Park, we took the gastric response to standard meal over a long period to get the average, and then we start the thyroid feeding. We have repeated it over long periods on a number of dogs. It is to be remembered, however, that the dog seems to be more resistant to the effect of thyroid than the human being. Thyroid extract in the dog decreases the gastric secretion, without causing any clear symptom of so-called hyperthyroidism in man, except possibly a slight rise of basal metabolism. I question the actual causal relationship between these so-called hyperthyroids and the cases of disturbed gastric secretion that are reported. Dr. Lockwood spoke of diabetes insipidus and of pituitary injection as throwing light on possible gastro-intestinal disturbances in endocrine disorders. I offer a plea and a protest to the effect that while diabetes insipidus is controlled by the administration of pituitary extract, the evidence is that the cause of the malady is injury to the base of the brain. We have no reliable evidence that pituitary extract is secreted into the blood in any condition.

Dr. Bruce C. Lockwood, Detroit: I did not have time in this paper to include the gonads or disturbances occurring at the menopause. I am aware, as Dr. Carlson has spoken, that diabetes insipidus is now considered as due to a brain injury rather than to an endocrine disturbance; but since it had been so long considered an endocrine disorder I included it in this series.

THE PREVALENCE OF TYPHOID CARRIERS IN A GENERAL POPULATION *

S. W. WELCH, M.D.
SOPHIE A. DEHLER, A.B.
AND
LEON C. HAVENS, M.D.
MONTGOMERY, ALA.

The examination of the general population for typhoid carriers in various localities in the past has disclosed an incidence, where the disease is not unduly prevalent, of from 0.3 to 0.8 per cent.[1] These results are based largely on a single fecal examination. Obviously, the urinary carrier and many intermittent intestinal carriers are missed. The difficulties attendant on the successful demonstration of a typhoid carrier are well known. Not only must fairly large numbers of the bacilli be present in the specimen, but also their numbers diminish very rapidly and any delay in the study of the specimen decreases the chance of a positive result. Repeated examinations of the specimen are therefore useless, and success depends on an immediate single plating of the stool. It is evident, then, that if the rapid diminution of the typhoid organism in the feces could be largely prevented, the laboratory examination would become much more valuable and repeated platings of the specimen could be made with increased chances of success.

[1] Gay, F. P.: Typhoid Fever, New York, p. 124, 1918.

The method used in the survey described in this paper prevents in considerable degree the rapid death of the typhoid bacillus in the feces; promotes, on the other hand, its multiplication and prevents, in most specimens, the rapid overgrowth of *B. coli*. This method has been described elsewhere,[2] but certain modifications have been made in the original method, and they are given here

The basic medium consists of bile, 1 liter; beef extract, 3 gm and peptone, 10 gm. The reaction is adjusted to p_H 7.2. If the medium is diluted 1 : 20, the color of the bile does not interfere with the indicator, and phenolsulphonephthalein may be used. The medium is then sterilized at 15 pounds for fifteen minutes. Brilliant green is then added in a concentration suitable to inhibit members of the colon group of organisms and not to prevent the growth of the typhoid bacillus. This should be determined for each lot of the medium by the addition of a small amount (not more than 1 gm.) of fresh feces to 15 c c. quantities of the bile medium containing brilliant green in varying concentrations The feces are seeded with small numbers of typhoid bacilli (from 100 to 1,000). The specimens are left at room temperature, and a loopful is plated from the surface of each on successive days. Our experience indicates that the usual concentration of the dye for the purpose lies around 1 : 1,500, but it is necessary to make this preliminary experiment with each lot of the brilliant green-bile to be sure that it is properly adjusted to prevent overgrowth of the typhoid bacillus with fecal bacteria, and to permit multiplication of *B. typhosus*.

TABLE 1—*General Results of Survey*

Number of persons examined ..	1,076
Number of specimens examined .	4,950
Number of persons positive (typhoid and paratyphoid A and B)	55
Number of specimens positive (typhoid and paratyphoid)	72
Per cent of persons positive (typhoid and paratyphoid A and B).	5.1
Per cent of specimens positive .	1.4
Average number of times each person was examined urine	2.3
Average number of times each person was examined feces .	2.3

The proper concentration of brilliant green having been determined, the dye is added to the bile medium The container used is a 1 ounce, wide mouth bottle containing about 15 c c of brilliant green-bile The following points are essential to the success of this method:

1 Large amounts of feces will decrease the activity of the dye and permit overgrowth of *B coli* Not more than 1 gm of feces in 15 c c quantities of the brilliant green-bile is a satisfactory amount

2 Incubation of the specimen at body temperature apparently encourages rapid overgrowth with fecal organisms, and, since the typhoid bacillus grows well at ordinary room temperatures, the specimens are not placed in the incubator

3 Most specimens of bile are well suited to an abundant growth of *B typhosus* Occasional lots of bile have been encountered, however, in which the typhoid bacillus fails to grow well This has been observed with both dehydrated and fresh bile The addition of beef extract and peptone permits satisfactory growth of the typhoid bacillus, but samples of the medium should be inoculated with *B typhosus*, both before and after the addition of the dye, to determine its ability to support growth

For urine cultures, from 5 to 10 c c of urine is used. Incidentally, the dye does not interfere with the use of the medium for blood cultures

LABORATORY EXAMINATION

On receipt of the specimen, Endo plates were streaked with a loopful from the surface of the bottle This was repeated on the two succeeding days, three platings being made for each specimen. Suspicious colonies were picked to Russell double sugar agar, carbohydrate reactions and agglutination tests being made on cultures from the Russell tubes which gave a characteristic appearance No culture was considered positive that did not agglutinate in high titer with a known monovalent agglutinating serum of high titer (from 1 : 10,000 to 1 : 20,000).

RESULTS

The survey included 1,076 healthy persons employed in the dairy industry of Alabama There were 1,004 men and seventy-two women Both feces and urine were obtained from each person an average number of 2.3 times Table 1 summarizes the results

Thirty-nine healthy typhoid carriers, thirteen paratyphoid A carriers and three paratyphoid B carriers were found, making a total for both typhoid and paratyphoid of fifty-five, or 5.1 per cent. Three hundred persons in a community where, until a few years ago, a very high typhoid rate existed, yielded thirty-one carriers If these are excluded from the general survey, there still remain twenty-four carriers of typhoid and paratyphoid among 776 persons, or a rate of 3.1 per cent.

Table 2 shows the distribution of fecal and urinary carriers. The number of urinary carriers is surprisingly high, almost one half of the total, indicating the importance of examining the urine as well as the feces in a search for carriers. The importance of enrichment of the whole specimen of urine, together with an incubation period to permit multiplication of the organisms present in the original specimen, undoubtedly yields a larger number of positive results than direct plating This preliminary enrichment and incubation is emphasized by Garbat[3] as an important part of the technic of urine examination for typhoid

The typhoid carrier rate that has been found to exist in certain communities in Alabama is much higher than any previously recorded This study, however, presents certain differences from those heretofore made Not only were specimens of urine as well as feces obtained, but repeated examinations were made An analysis of the positive results shows that thirty-four carriers were found on the first examination Subsequent examinations resulted in the detection of twenty-one additional carriers who would have been missed had only a single specimen been obtained Furthermore, it is seen in Table 2 that there were eighteen urinary typhoid and five urinary paratyphoid A carriers If feces only had been examined these would, of course, have been missed, leaving only eleven carriers, who would have

been detected by a single examination of the feces, or a rate of 1.0 per cent

That typhoid carriers in general do not excrete the bacilli in large numbers at all times is indicated by the well known difficulty of obtaining bacteriologic proof of a carrier Further evidence of this intermittence is offered in Table 3. This table shows the number of examinations, the period covered by the examinations and the specimens that were positive. It further emphasizes the importance of repeated examinations, and illustrates the fact that no definite number of examinations will exclude the possibility of the existence of the carrier condition. In three instances (35, 36 and 37), positive results were not obtained until the sixth examination. Subject 8, a urinary carrier, had three negative examinations before a second positive specimen was obtained

* Both feces and urine

This high typhoid carrier rate in a general population cannot be given its proper significance until a more complete knowledge of the carrier problem in general has been developed. It is evident that no outbreak can be traced to the majority of these carriers. It must be assumed, for administrative purposes, that every person who harbors bacilli that conform to the cultural and serologic criteria of the typhoid bacillus is a potential disease producer That such a person actually does cause disease is another question. Personal habits may determine to a considerable degree the effectiveness of a carrier in producing typhoid fever. There are included in our series two urinary carriers, the owners and operators of a dairy, to whom no case of typhoid fever can be attributed over a period of at least five years. These two carriers have been particularly cleanly in their habits, and even though engaged daily in handling milk consumed by others, apparently prevented the infection of their product over this considerable period of time. One of these carriers could give no definite history of an attack of typhoid; the other had had typhoid fever fifteen years before.

It must further be assumed that all these organisms are virulent. Had we a test to determine the virulence of typhoid cultures, it might be found that many typhoid carriers are harboring avirulent bacilli, incapable of disease production.

As the result partly of the difficulty of detecting the typhoid bacillus in the discharges, it is assumed that a healthy carrier is a permanent carrier. It is possible that exposure of immune persons to infection may produce a temporary carrier state more frequently than has been actually supposed. Klinger and Lentz[4] adduce some proof of the existence and temporary nature of so-called contact carriers. Klinger found eleven carriers in the neighborhood of cases of typhoid fever who gave no previous or subsequent history of an attack. In nine of these the bacilli were found on only one occasion. Lentz examined persons in association with typhoid patients and discovered twenty-two carriers Semple and Greig[4] report the finding of carriers among hospital orderlies in attendance on patients with typhoid

Regardless of these considerations, it is apparent that many typhoid carriers exist against whom there is no epidemiologic evidence of responsibility for disease production This high carrier rate in a general population may indicate that a larger proportion of cases become carriers than has previously been supposed. A study of patients who have recovered is now being made in Alabama with this point in view.

SUMMARY

The method described for the collection of specimens of feces and urine for typhoid cultures prevents in a large measure the deterioration in value of such specimens with the lapse of time. A typhoid carrier survey of 1,076 healthy dairy employees yielded fifty-five carriers of typhoid and paratyphoid bacilli, a rate of 5.1 per cent.

519 Dexter Avenue.

ABSTRACT OF DISCUSSION

Dr Seneca Egbert, Philadelphia It is agreed that there is a difference between the danger of contagion from the carrier in the city and the carrier in the country In the city where there are all the conveniences of the home and household, such as good plumbing, and where the discharges of the body go into the common sewer and are later well diluted or treated and no longer dangerous to health, the carrier may not be a menace, but in the country the excreta of the carrier often go to a cesspool and then into the drinking water of the household I think that the question of household conveniences is a factor in these cases and frequently determines whether a carrier is a serious menace or not

Dr George M. Kober, Washington, D C: It was my pleasure to make a tabulation in 1895 of 330 epidemics of milk-borne typhoid fever, scarlet fever, diphtheria, septic sore throat, etc I am very glad that Dr Welch has investigated the subject of typhoid carriers in relation to the milk supply.

---

[4] Quoted by Ledingham and Arkwright The Carrier Problem in Infectious Diseases, London, p 19, 1912

I have always felt that after convalescence from typhoid fever we should know more about the percentage of typhoid carriers. I feel that it is highly important that more such surveys should be made. I came to the conclusion in 1895 that the safeguarding of the milk supply was one of the most important sanitary problems. I feel that perhaps the most efficient preventive measure that we as sanitarians can offer to the public at large is by advocating sterilization or pasteurization of all cow's milk. Many physicians are opposed to this on the assumption that heat destroys the vitamins and impairs the digestibility of the milk, but even there we have been assured by experiments that rapidly heated milk does not to a degree affect vitamins and it has been shown by Dr. Schroeder of the Department of Agriculture that heated milk does not impair its digestibility. So on the whole I don't know that we can offer any better advice than to bring up the milk rapidly to the boiling point, or what is commonly called scalding it.

Dr. W. H. Seemann, New Orleans: I do not know of anything that the rise and fall of the health officer is more largely governed by than his typhoid rate. Day by day we are getting closer to the question of the individual carrier. We do not know what cesspools, water supplies or food supplies may be infected. In this way we have outbreaks. Work must be done with the man who handles foodstuffs, the starting point of an outbreak, and the method Dr. Welch has outlined for rapidly determining the existence or nonexistence of the carrier state seems to me to be a very valuable one. We have been for many years using various inhibiting agents. The big point he has brought out in hunting for typhoid carriers is rapid planting in whatever culture material one may use. In addition, it has been noted that excretion of typhoid bacilli in carriers is not always a constant process, but at times the bacilli will not be found in urine and in the feces, when on another occasion they may be found.

Dr. A. J. Chesley, Minneapolis: In Minnesota, only two small outbreaks of typhoid have been water-borne since 1914. The division of preventable diseases has systematically followed up epidemiologic indications of carriers since 1913, and to date has discovered 131 carriers responsible for 644 cases, including forty-six fatalities. Mailing outfits with a medium like the one Dr. Welch describes are used for sending specimens of bowel and bladder discharges to the laboratories. The control of typhoid carriers must be carried out without publicity if possible. In cooperation with the state dairy and food department, a program for typhoid carrier supervision was agreed on several years ago. The 131 carriers were discovered through investigation of outbreaks traced to them. Occupation is an important factor in relation to typhoid carriers. Dairy workers, then cooks and food handlers are most dangerous when carriers. What automobile tourist traffic may show remains to be seen; but many people who ordinarily do not handle food prepare it for others while touring. It is often impossible for a dairy farmer or a cook to give up his work and get something that is safe with an income sufficient to support his family. Whenever possible, certain adjustments have been made to permit the sale of cream, separated at the farm, to supervised creameries where it is pasteurized and used for butter making only. Sometimes no adjustment can be made and the carrier suffers serious losses entirely in the interest of public health. The 1925 legislature granted $6,000 a year to be used by the industrial commission at the direction of the state board of health to aid carriers who suffer serious losses. A bill for typhoid carrier relief had been considered at several previous sessions. In 1925 the bill was not passed, but the appropriation was granted. This typhoid carrier appropriation by the legislature I think is a distinct advance in practical typhoid control. Typhoid infection always comes from a patient, a convalescent or a chronic carrier as far as we know. Therefore, when water supplies are properly safeguarded, the epidemiologic search for carrier sources of outbreaks with intensive systematic follow-up of typhoid convalescents should eradicate typhoid fever. And the injustice now done to the carrier and his family may be lessened by state compensation in deserving cases.

Dr. A. T. McCormack, Louisville, Ky.: I congratulate Minnesota for recognizing human beings in the same way as dairy cows. This is a real milestone in progress which really indicates that the human being will be considered of some cash value along with other animals for which we are in the habit of paying in money.

Dr. S. W. Welch, Montgomery, Ala.: We have in the last two years organized a movement for the standardization of the milk control methods in Alabama. Some years ago we standardized the control of our municipal water supplies. We concluded that we could now standardize our milk supply, and if we could do this, we would have our principal sources of typhoid fever under control. The work that we have done has given spectacular results. In 1907, when we began this work, we had 989 deaths from typhoid fever in the state. In 1924 there were just a few more than 300. We have no municipal typhoid fever worth mentioning now. We have made some very interesting discoveries. Outbreaks of typhoid fever in rural districts on investigation have practically every one of them been traced to a carrier. We are now conducting an organized campaign against carriers. We have obtained some very startling results along these lines. While admitting that the carrier is the cause of most of the typhoid fever in rural districts, I am not prepared to admit that they are without danger in the city. Our first knowledge of the carrier was Typhoid Mary. Any one who handles food supplies, whether in the city or country, is a potential distributer of typhoid fever. We are examining our food handlers in every capacity in Alabama with a view of eliminating all who proved to be typhoid carriers. The discoveries have sometimes been disconcerting. A man and his wife, who had been conducting a dairy for five years, were found to be carriers and the dairy closed. There seemed to be nothing else to do, although we did not trace typhoid fever to any one who had been supplied with milk from his dairy.

IMMUNITY IN CANCER*

FRANCIS CARTER WOOD, M.D.
NEW YORK

For years the fact has been noted that occasionally human carcinoma or sarcoma disappears either spontaneously, after incomplete removal, or in connection with some general processes. Among the latter may be enumerated high and continued fever, or profound alterations in the metabolic processes of the organism, such as cachexia, artificial menopause, or the puerperium. While doubtless many of the older observations are unreliable because of the lack of microscopic tumor diagnosis in the period during which the patients were observed, there are still in the literature some hundreds of examples in which a microscopically verified, morphologically malignant tumor disappeared for a period of years. But during the thirty or forty years that these recessions have been observed to occur, millions of people have been recorded as dying of cancer, so the phenomenon must be extraordinarily infrequent and conclusions as to the underlying causes can scarcely be drawn. According to my experience, tumors resembling sarcomas, but difficult to differentiate microscopically from the granulomas, are the type most likely to regress. The records show that very few typical carcinomas have undergone spontaneous regression for any extended period. A slightly different aspect is seen in very late node or scar recurrences, following chiefly radical mastectomy for carcinoma. These are not very infrequent as late as fifteen years after the operation. A few similar late recurrences have been observed after the removal of malignant growths from other situations. A valuable recent collection of many of the first group can be found in an article by G. L. Rohdenburg.[1]

---

* From the Institute of Cancer Research, Columbia University.

* Read before the Section on Pathology and Physiology at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

The fact that some of these regressions were coincident with bacterial infections, especially erysipelas, has led to the attempt to cure cancer by the inoculation of virulent erysipelas germs; but a number of deaths having followed this method, it has long since been abandoned. On the other hand, Coley has for years advocated the therapeutic use of a fluid containing the toxins of the erysipelas streptococcus plus those of *Bacillus prodigiosus.* He has used this in a very large number of cases of sarcoma, having found that it was ineffectual on carcinoma. A certain number of regressions have been reported by Coley and others, but they are small in number compared with the many failures. Evidently the procedure is not an effective remedy.

Many attempts have been made, using the analogy of the potency of bacterial vaccines and antitoxins, to induce immunity against human neoplasms by injecting either antiserums produced by treating an animal with the neoplasm, or by direct inoculation either of the crushed tumor or of a tumor killed by roentgen ray. Neither of these methods has proved effective and the last two are dangerous, as examples are known of massive production of tumor tissue in the unfortunate patient, because some of the cells escaped either complete crushing or destruction from the roentgen ray. None of the vast number of serums, either normal or obtained from cancer patients with a quiescent growth or containing the antibodies produced by some hypothetic cancer germ, have proved of the slightest value, nor has it ever been possible to demonstrate in the body either of human beings or of animals any reaction that can be regarded as a response to an immunizing quality of the tumor cells of a primary growth of whatever nature. Even the successful transplantation of a tumor from one animal into another healthy host of the same species, and the continued growth therein, does not result in any demonstrable antibody, though we do occasionally see such antibody production in the course of transfusion in human beings, when the first injection has gone smoothly but the second from the same donor has produced a serious reaction, often accompanied by extensive hemolysis. Evidently, then, the cells of primary tumors are extremely closely related to the tissues of the host and, therefore, are neither more nor less susceptible to the influence of the processes of immunization than the homologous tissues of the body.

If the cause of such spontaneous disappearances cannot be traced to the action of the host on the tumor cells, are there any other facts that may explain the phenomena? The poor vascularity of many malignant growths, and the thrombosis that often occurs in the vessels of a tumor, not infrequently give rise to extensive necrosis, to resorption of the necrotic material and thus to a clinical regression. Such clinical regressions, however, are usually followed in due time by a fresh outburst of the tumor, which then runs its usual course.[2] When, however, scarring occurs about the neoplasm, the return may be delayed for a long period. This is best seen in the very late returns observed after the caustic cure of squamous cell epitheliomas of the face and lip, for recurrence may be very slow. In some instances, years may elapse. The low malignancy of many tumors in the aged is another evidence that with lowered metabolic activity the tumor growth may be slow but is not inhibited. For if there were such inhibition, tumors would not be more frequent in the old than in the young.

The interest in the subject of tumor regression has been greatly stimulated of late by the active research on the general biology of cancer that has been carried on in various laboratories and by an attempt to find out the method of action of radiation on the cell.

For a long time after the introduction of the roentgen ray and radium as therapeutic agents, such effects as were produced on malignant structures were regarded as a direct action of the rays themselves, and the surrounding normal tissues were considered to play, so to speak, a neutral part in the process, though the earliest observers noted that lesions were frequent in the terminal arterioles and much connective tissue sclerosis present. These arterial changes diminish the nutrition of the tissue so affected, and thus cut down to a certain extent the supply of food to the cancer cells contained in such sclerotic tissue. But this, while very important in the primary reduction in the size of tumors, does not destroy all the cells of a growth, and it has been generally accepted as purely a secondary process and has not been regarded as exerting any destructive action against the cancer cells. In recent years, however, especially since the fact has been observed that animal tumors require exceedingly large doses of radiation to kill all the cells, and since a considerable amount of human pathologic material has been examined showing that even with a clinical cure, apparently viable tumor cells remain in the tissues for long periods, the hypothesis has been favored that a large part of the action of radiation is indirect; that the cancer cells are merely damaged, and the destruction completed by some sort of activity on the part of the surrounding tissues. It is impossible to record, within the limits of a paper of this type, a complete summary of the different ideas that have been held by various workers, both laboratory and clinical. Only the most important contributions can be included. But the question is so fundamental to the intelligent application of radiation methods in the treatment of cancer, and the interest in the results of these is so universal, that a survey may be useful.

The question is, then, What is the mode of action of the rays of radiation on the cell? Is it a direct destruction, or is it in part direct action and part a stirring up of the protective agencies of the body such as come into play, for example, in the bacterial infections; or may such results as are observed be wholly due to such protective agencies?

In the first enthusiasm for radiation therapy, the question of anything but direct destruction was not considered. But when those employing these agencies recognized that there were extensive limitations to the curative capacities of irradiation, and when it was shown by myself and verified by others that animal tumors when irradiated inside or outside of the body required very heavy dosage to kill all the cells, those who believed that they could cure cancer added the new hypothesis that the body had some destructive capacity which aided the direct action of the radiation and destroyed such cells as had not been killed by direct action. A very active study of the question immediately began and assumed two forms: the laboratory experimental work on primary and transplanted tumors in animals, and careful clinical and histologic investigation of the results of irradiation on human tumors.

STUDIES ON ANIMAL TUMORS

One of the first to study the conditions surrounding the spontaneous disappearance of animal tumors was da Fano, who published reports of very careful histologic investigations showing that such regressing tumors were often, though not always, surrounded by a dense infiltration of lymphocytes and plasma cells. He drew the very cautious conclusion that there was some correlation between the presence of these cells and the disappearance of the tumor. This was later taken up by Murphy and his co-workers on a very large scale at the Rockefeller Institute. They published a series of papers containing many ingenious methods of investigation of the problem. They worked, however, chiefly with one tumor, known as Bashford 63. It is not altogether a satisfactory tumor for this work, as it takes irregularly, sometimes 100, sometimes 90, sometimes 80 per cent., and also disappears spontaneously in an unpredictable proportion and often leaves the animal immune. Sometimes the disappearances may amount to 50 per cent. of the inoculated tumors; at other times to less. The use of such a variable tumor—and these variations cannot be removed by the use of a pure bred stock—makes it very difficult to draw definite conclusions unless the effect of these variations is removed by the use of a very large series of animals for each experiment. The conclusions drawn from such experiments cannot be transferred to other transplantable animal tumors, nor can they in any way be considered as warranting conclusions concerning primary human tumors, because the latter practically do not disappear spontaneously. Murphy found that irradiating animals caused a general and local lymphocytosis, and that after such a lymphocytosis was induced a resistance to tumor implantation could be demonstrated. Assuming, for purposes of discussion, that the results of all of Murphy's experiments are correct, in order that the facts so obtained may be generally applicable they must first be verified on other animal tumors. The following work was done in this line at the Institute of Cancer Research of Columbia University.[3] I quote the following conclusions from that paper:

> 1. Assuming that the lymphocytes carry protective substances, mice or rats with lymphatic leukemia or very high leukocyte counts, 20,000 to 30,000, should show some immunity to tumors. This is not the case with a number of animal tumors, including Sarcoma 180, the Flexner-Jobling rat carcinoma, and incidentally was not observed in the case of human lymphocytic leukemia with a carcinoma of the cervix. The growth progressed at its usual rate and the patient died. Neither Sittenfield nor Kelling was able to show that an artificial lymphocytosis had any effect on tumor growth.
>
> 2. If grafts of normal tissues are destroyed by lymphocytes, a preliminary reduction of the total leukocyte count, especially by means of x-rays or radium, should result in a greater number of takes. This we have not been able to demonstrate, even when many hundreds of grafted animals and controls were used. The thyroid gland was the organ used for the grafting.
>
> 3. In this same connection it was important to determine whether a tumor of very low growth potentiality could be influenced by the destruction of the lymphocytes. Such a tumor is a guinea-pig fibrosarcoma now being transplanted in the Crocker Fund laboratory. The percentage of takes in this tumor is very small. The animals were x-rayed previous to and following the inoculation of the tumor, the site of the growth being protected by lead. No increase in the number of takes was observed.
>
> 4. The effect of the reduction of the lymphocytes in the circulating blood on the rate of take of tumors was studied, first with standard transplantable tumors, second with primary tumors inoculated into a series of animals, half of which were rayed, the raying being either light or very heavy. Not the slightest difference could be observed over a considerable series of experiments between the rayed and the unrayed animals.
>
> 5. Finally, the raying of *rats* in which a highly virulent *mouse* tumor had been implanted did not prolong the life of the tumor.
>
> It is therefore evident that the lymphocyte is in no way correlated with cancer immunity.

Opitz at first thought he had demonstrated immunizing effects by irradiating the whole animal with small doses, but in his last paper shows that they were not constant.

Caspari[4] has also attempted to demonstrate the conditions that underlie the disappearance of inoculated tumors. He believes that the death of the tumor cells sets free a nonspecific substance which he calls a necrohormone, which interferes with the further growth of the tumor; but he fully realizes the complications that underly the study of the situation and that no specific antibody like those which are developed against bacteria plays any part in the tumor immunity. Regaud also believes that a toxic substance is set free in the tissues which has a lethal effect on the tumor cells.

Mottram and Russ[5] believe that irradiation incites an immunity, but they used the Jensen rat sarcoma, which is a very variable tumor, often disappearing spontaneously in a high percentage of untreated animals.

Baensch[6] does not agree with Opitz that there is an action of roentgen rays on the vegetative nervous system and through this an unfavorable effect on carcinoma. That writer was also unable to confirm in human beings Opitz' experiments on mouse tumors which receded when the tumors were protected from the roentgen rays and the rest of the animal was irradiated. On the contrary, when a malignant tumor in man was covered and the surrounding tissue—for example, the entire thorax—was irradiated with moderate or large dosage, not the slightest effect was observed.

Kok[7] has recently summed up his work with Vorländer. The effect of irradiation over the entire animal is most effective when it is carried out from two to three days after the tumor has been grafted. After the tumor has definitely begun to grow, the animal must receive at least one third of an erythema dose over the entire body to have any effect. This is a larger amount than can be given to a human being. His observations point to the fact, which has long been known, that grafts do not take well in animals that are sick, and after the operation. A few similar late recurrences have been observed after the removal of malignant growths from other situations. A valuable recent collection of many of the first group can be found in an article by G. L. Rohdenburg.[1]

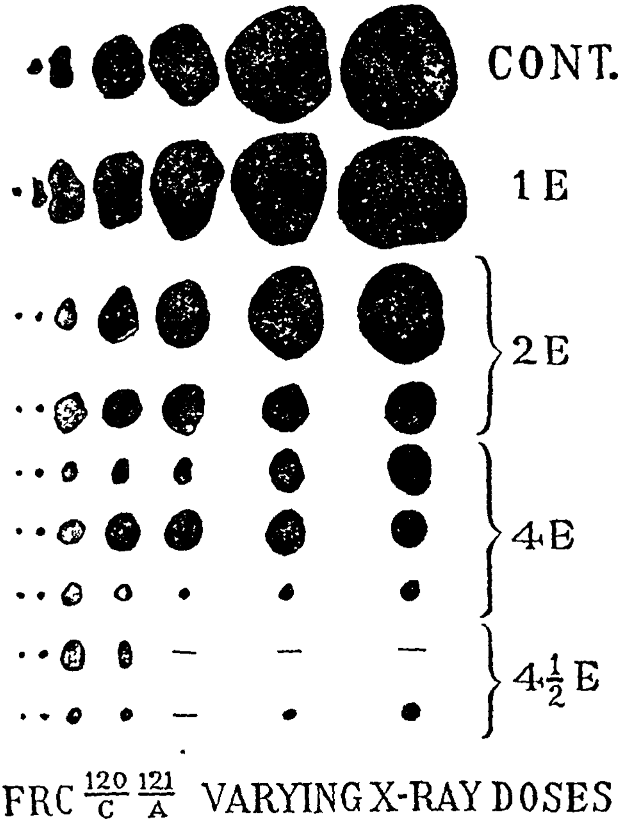
Keysser,[8] influenced by Seitz and Wintz' theory of a "carcinoma dose," irradiated a large number of animals with transplanted tumors and made the remarkable discovery that either the animal tumors have an entirely different biologic susceptibility to roentgen rays than the assumption of Seitz and Wintz concerning human cancer warrants, or that his dosage computations were incorrect, or that the action of the rays on the tumor cells must be an entirely indirect one. As Wintz has recently retracted his "carcinoma dose," saying that he never meant by a "carcinoma dose" that it was a dose that would cure cancer, but was merely a maximum which could be given to a cancer without danger to the patient, it is evident that the human tumors are not so different from the mouse tumors in their susceptibility. The second possibility, that the computations of his dosages were incorrect, may or may not be valid. Recent studies of the erythema dose of the various German clinics have shown that it varies as much as 350 per cent. Keysser rather leans to the explanation that there is a general protective reaction of the body which causes a destruction of the tumor.



Effect of different roentgen ray doses on the Flexner Jobling rat carcinoma: All outlines are scaled tracings of the tumor taken one week apart; roentgen-ray treatment was given after the third charting. Top line, untreated control, second line, tumor given one human skin erythema dose; third and fourth line, tumor given two erythema doses, fifth, sixth and seventh lines, tumor given four erythema doses, eighth and ninth lines, effect of four and a half erythema doses, which is about the lethal dose of the tumor One tumor is killed; the other disappears, but recurs later from a few remaining cells.

In further experiments he irradiated tumors in the animals, removed them immediately, and transplanted them. These transplanted tumors grew. But if the tumors were left in the animal's tissues for ten days and then transplanted, he obtained no takes. From this he drew the conclusion that the direct action is unimportant, and that the secondary action of the tissues, which occurs in the period during which the tumor remains in the body, is the important thing. Unfortunately this experiment is not conclusive, for at the end of ten days the destructive effect of the rays on the tumor cells has reached its maximum. If the tumor particle is then transplanted it is already a highly damaged tissue. The transplanting adds fresh trauma. As is well known, most of the cells in the grafts die and the take occurs from only a few remaining cells. It is probable, therefore, that in Keysser's experiment the explanation of a nontaking of the graft which remained ten days in the animal is that the damaged condition of the cells is responsible for the nontaking, rather than in a hypothetic destructive action of the surrounding tissues. For, if the graft, as my own experiments show, is given a sublethal dose, and instead of being transplanted is left in the animal, it will shrink considerably but ultimately recur.

Keysser gives no details except that he gave about two erythema doses. This is probably equivalent to three American erythema doses—an amount considerably below the lethal dose of mouse tumors. He apparently does not know whether the mouse tumor he used was capable of inducing immunity against itself—an important point.

I have gone over Keysser's work and get different results. Testing the matter with animal tumors, the following experiment seems to me a crucial one, and I fail to see any logical answer to the necessary conclusions that must be drawn from it. The first requisite was a tumor with a known lethal point to the roentgen ray. Radium is unsatisfactory because of the difficulty of measuring the exact dose reaching the tissue, owing to the rapid falling off of the dose with increasing distance according to the inverse square law, and the irregular form of the container, which requires complicated mathematical computations to give the exact amount.[9] But with a 40 to 50 cm. skin-focus distance and highly filtered roentgen rays, the beam is so nearly homogeneous and parallel when applied to a small tumor that the tissue absorption factor is low.

Take, for example, a series of experiments carried out in the Crocker Institute, using the Flexner-Jobling rat carcinoma. This, as I have shown some eight years ago, is killed at about four and a half erythema doses, all scatter being eliminated, and using the term "erythema" as a very light reddening of the human skin. The German erythema dose is from 50 to 100 per cent. higher than this. The rodent's skin will bear three human erythema doses without damage, but four are apt to produce some burning and epilation. If, now, grafts are planted on the outer surface at the thigh of a series of rats, and after the growth has reached a stable stage and the tumors are from 5 to 10 mm. in diameter they are irradiated, the following phenomena, recorded in the accompanying chart, are to be observed: One human skin erythema dose to the tumor alone produces no change. Even if the animal as a whole is irradiated, the tumor also continues to grow. If two erythema doses are applied to the tumor alone, practically no change in growth rate is noted. With four erythema doses the tumors grow more slowly, but still progress, and in no case disappear. In other words, if the tumor requires four and a half erythema doses for its destruction in vitro, it requires four and a half erythema doses to be killed in vivo. As a matter of fact, it ofen requires a little more, because the circulation of the blood through the tumor washes out the destructive products produced by the action of the rays on the cells, and, so to speak, rejuvenates the tissue somewhat. If there is any resistance, protective action or destructive action on the part of the connective or other tissues of the host, any effect on the tumor from the lymphocytes or plasma cells, it would diminish the amount of roentgen ray required to kill the tumor.

[9] Wood, F. C., and Prime, Frederick: Ann. Surg. 62: 751, 1915.

Recently we have repeated the work to find whether our animal tumors have changed their lethal dosage. We found that the tumors killed ten years ago with a definite amount of radiation are still killed with the same quantity and exposure in the same time. But in the course of this redetermination we were able to make a large number of experiments of this type. Hundreds of animals with different types of growths have been given one erythema dose to the whole animal, and not a tumor has disappeared; the only ones which have disappeared have been given that full lethal destructive dose required to kill the tumor outside the animal. I cannot see any other way to interpret this experiment but that the body plays no part in the destruction of the tumor by irradiation.

Murphy[10] recently reported a similar roentgen-ray experiment with somewhat different results, but the number of animals was small, the tumor was a primary one whose lethal dose was unknown, and the irradiation was done only ten days after grafting, a period when the tumor is highly susceptible to injury, as its vascular relationships are as yet not thoroughly established. The rays used were the very soft, unfiltered, and the time only 150 seconds. There are many probabilities of error in using such rays at a distance of only 5 to 10 cm. from the tube and for so short a time, and there is no evidence in Murphy's paper that care was taken to eliminate such sources of fluctuation. The most important of these is that the absorption of such soft rays is so great that the proximal surface of a tumor may receive a lethal dose, the cells of the distal portion being practically unharmed. Grafts taken from top or bottom of the tumor may hence give inconstant results. His conclusions, therefore, cannot be accepted as generally valid unless obtained under more accurately controlled conditions, and we have never been able to duplicate them in this laboratory.

Nor do I think that the conclusions of Nakahara[11] in this connection are valid. He irradiated an animal and then implanted tumors in the irradiated areas, and noticed that the tumors did not take in all instances. The number of transplants, however, was small and the tumor used was one with a great variability in the number of takes even when untreated. Having noticed pycnotic and other changes in the nuclei and the formation of monstrous cells, he makes the assumption that, since the morphologic changes in the tumor are those characteristic of the roentgen ray, it is the irradiation of the tissues that has produced the changes in the tumor cells. He does not seem to be aware of the fact that these changes are not at all characteristic of the roentgen ray, and may be produced by any physical agent, such as heat, either by directly warming the tissues in a water-bath, or by diathermy, or freezing of the tumor in the animal, and also by certain chemicals. His descriptions and photomicrographs are merely those of damaged or dying tumor cells. In such experiments, some of the tumors unquestionably die because the connective tissue, after it has been irradiated, does not react to the presence of a graft with the formation of blood vessels as easily as does the uninjured structure. As the fate of a graft depends entirely on its prompt vascularization, as has been shown by Jensen and confirmed by others, the fact that all the grafts did not take is simply more evidence of this fact.

If this experiment is repeated with a tumor of high virulence, like 180, not only does the tumor take in its usual percentage of 95 to 100, but the growth shows no morphologic alterations. The same is true of the Flexner rat carcinoma. *Evidently the general conclusions of Nakahara are not warranted from his experiments.* All such merely morphologic studies are difficult to interpret. The assumption that, because lymphocytes are present and the connective tissue grows into the receding tumor, the lymphocytes and the connective tissue are the causes of the recession, is an assumption which is no more justified than that cirrhosis of the liver is caused by the choking of the liver cells by the connective tissue that grows in between them. As a matter of fact, no pathologist today would make such a statement, every one knowing that the damage to the liver cells occurs first, and that the fibrosis is merely a replacement. That such cirrhotic fibrosis may compress the portal vein and cause ascites is another question. That is a secondary action, just as the connective tissue which forms through a tumor as the tumor cells disappear may produce a firm scar which shuts off many of the remaining cells from their nutrition, and may ultimately be responsible for the death of a certain number. The cells of a human scirrhous carcinoma of the breast seem to have the capacity to incite abundant growth of connective tissue; yet such a tumor does not cure itself.

We cannot escape from the fact that as far as animal experiments go there has been no proof as yet brought forward that the effect of irradiation on a tumor is anything primarily but a direct effect on the cells. Secondary effects by thrombosis of the vessels are unquestionably important, as the following experiment shows:

If four 1 mg. platinum needles are inserted in a square in an animal or a human tumor at a distance of 1 cm. apart, the tumor tissue between those needles will necrose after from 90 to 100 milligram-hours. The tumor tissue outside the needles will not necrose, unless the time the needles remain is something equivalent to 700 mg. hours, which is the lethal dose of radium with a tube 3 mm. from the tissue with the given filtration, a dose equivalent to five erythema doses to the human skin. Microscopic examination shows quite definitely why the tumor cells between the needles die with a dose insufficient to kill such tumor cells in vitro, and the reason for this is thrombosis of the blood vessels. The reason the tumor cells outside of the area included by the needles do not die is that an insufficient dose has been given to kill the cells directly, these cells being nourished by the large vessels coming from the periphery of the neoplasm.

STUDIES ON HUMAN MATERIAL

Ewing, Alter[12] and others have made careful histologic investigations of material removed surgically after radium therapy, and have found much the same histologic pictures of lymphocytic and plasma cell infiltration around receding masses of tumor cells that were observed in the experimental studies on animals, and hence have concluded that this tissue reaction was important in cancer regression of the tumor.

Ewing[13] speaks in no uncertain way concerning the defensive reaction of the body and tissues. In the paragraph cited, he is speaking of the regression of metastatic carcinoma of the testes and embryonal tumors of the ovaries, lymphosarcoma, mixed tumors of the salivary glands, and so forth, and says that when employing less than the killing dose and repeating the exposures at intervals, most of the embryonal and lymphoid tumors react as well as with very heavy doses. "The process leading to these results has certainly not been the direct destruction of tumor cells. . . . It seems more probable that cell autolysis and growth restraint, aided by the natural defense reactions of the body, combined to bring about a gradual regression and eventual disappearance of the tumors." He grants, however, that in the adult type of tumor, such as recurring mammary cancer, uterine and intestinal carcinomas and most osteogenic tumors, external irradiation has been mainly palliative, and that while the life of the patient has been prolonged, the tumor has not been eradicated. He also states that "inasmuch as no form of radiation yields any great success in debilitated or cachectic subjects, it must be evident that radiation therapy relies heavily upon the healthy reaction of the affected tissues and the whole organism."

Again he[14] says:

> The conception of a standard dosage seems to emanate mainly from the notion that radiation cures cancer by killing cancer cells. The idea is an inheritance of the old surgical point of view, that the cancer must be extirpated, root and branch. Thus the experimentalist places a fragment of cancer tissue in a dish, exposes it to radiation, transplants it back into an animal and calculates the killing dose when it fails to grow. This type of experimentation has a definite and somewhat important place, but as an adequate basis of clinical deductions it has seldom escaped criticism when presented before scientific bodies. It has repeatedly been pointed out that such experiments wholly fail to take account of the reaction of the living tissues, which is the main element in the selective cure of cancer by roentgen ray and radium. We are therefore compelled to review our knowledge of the mechanism of the action of these physical agents in causing the regression of cancer.

Alter, on the contrary, believes the connective tissue reaction to be entirely secondary to the destruction of the tumor cells, and only of a reparative nature, taking no active part in the death of the neoplastic structures.

Among recent clinical papers favoring the view of the resisting power of the tissue is one by Drs. Evans and Leucutia.[15] Their conclusions, apparently largely inspired by Murphy's last paper—though clinical observations are also cited—are that there is a beneficial action of roentgen rays in the postoperative stage of mammary carcinoma; that a local tissue reaction is produced by suitable irradiation which brings about immunization against the carcinoma, and that excessive doses will destroy the normal protective tissue about the lesion and aggravate the disease.

On the other hand, many students of the subject have found that even with tumors of the skin viable cancer cells remain in the scar following an apparent cure with irradiation. Operations on patients who have been apparently cured of a malignant growth by irradiation and in whom the growth has been quiescent for a considerable period of years are often disastrous, owing to the rapid recurrence of the growth in the line of incision, so that there is a considerable body of evidence that despite the production of a clinical cure, viable cancer cells remain shut up in the dense scar tissue produced by the radiation. This does not prove that some of the cells may not be killed by the inflammatory reaction which the radiation sets up, but it casts considerable doubt on the effectiveness of the assumed protective agencies. The fact that, as previously stated, metastatic particles of carcinoma may remain in scar tissue or in lymph nodes for many years after the removal of a primary growth of the breast demonstrates that the healthy tissues have but little destructive capacity. The fact brought out by M. B. Schmidt that many cancer emboli do not survive and form metastases in the lung is an entirely different phase of the question. Failure to grow means that the cells are, by the coat of fibrin which surrounds them, mechanically prevented from attaching themselves to the wall of the vessels and thus obtaining the necessary capillary blood supply essential to their growth, and shows also that the respiratory motion of the lungs may play an important part in preventing the same sort of adherence to the vessel wall. Another illustration drawn from the laboratory is seen in the spleen, which is rarely involved by embolic tumor particles. But if a graft is placed directly in the organ, it grows with great facility. In human material, too, it is frequently observed that a tumor—for example, of the pancreas—may involve the spleen by direct extension and grow well in its substance, while, as is well known, embolic involvement of that organ is somewhat rare in man.

Jüngling[16] has brought forward a number of clinical observations which strongly suggest that the action of irradiation is purely a destructive one on the cell, for he has irradiated superficial carcinomas, protecting a portion of the growth by a narrow strip of lead, and then removed sections and examined them microscopically. He has found, for example, that the action on such cells is purely local and that even if a large dose was given which destroyed the cells, a strip of lead only a millimeter or two wide so protected the cells underneath it that they were apparently not damaged.

Jüngling concludes that the action of the roentgen ray on cancer is purely local and that the assumption of destructive action due to inflammatory changes is untenable.

Fischer[17] has made observations similar to those of Jüngling.

Wintz, in discussing Jüngling's paper, says that irradiation in small doses, intended to incite a growth of the connective tissue with an idea of choking the cancer cells, is useless, for the connective tissue has no such power but merely replaces the cancer cells after they are destroyed by the direct action of the roentgen ray.

Von Gaza[18] also says there are no observations which point to the fact that mesenchymal cells can attack healthy ectodermal or endodermal cells or their derivatives. The epithelium first must be killed and then may be attacked by mesenchymal phagocytes, and he elsewhere states that it is certain that the most active mesenchymal cells cannot attack healthy living cells such as those of uninjured cancer, and again, that the theory of a successful activation of the mesenchymal tissues against carcinoma without simultaneous severe damage of the tumor cell is without any support from morphologic studies. The only effect which is possible is that the mesenchymal proliferation shuts off the food supply, for example, by vascular lesions, and thus causes the necrosis of the cancer cells.

In a number of articles from the Mayo Clinic by MacCarty and his colleagues,[19] attention has been called to the relation between postoperative longevity and lymphatic infiltration. He says that in a small series of cases which could be thoroughly studied, the presence of extensive lymphatic infiltration by the cells of the tumor was correlated with a longer life, both in carcinoma of the stomach and in carcinoma of the rectum. Additional factors are fibrosis and hyalinization of fibrous tissue. When these are well developed, the prognosis seems to be better. MacCarty is, however, extremely cautious in assuming any causal relationship, and justifiably so, as it is perfectly possible that the lymphatic reaction and the fibrosis are secondary to the presence of a carcinoma, and that they are most abundant in the types which are not highly malignant, and therefore stand in no causal relationship to the extension of life following operation. A reinvestigation of the question by Greenough and myself, using breast tumors, has shown no correlation between longevity and lymphocytosis on this material.

COMMENT

It seems to me that this somewhat lengthy survey of a few of the more important investigations of the question of the capacity of the body to produce immunizing substances against a growing cancer can be decided in only one way, and that is according to the Scotch verdict, "not proven." It is quite possible to explain most of the observed conditions without such an assumption. Late recurrences may be due to alterations in the biology of the tumor cells, and we know from experimental work that different parts of the same tumor may be composed of cells of different malignancy. Cells may remain quiescent in lymph nodes for long periods, probably because the conditions of nutrition are different from the ones to which they are accustomed when living normally surrounded by amply vascularized connective tissue. The mere study of fixed and stained tissue can scarcely bring decisive evidence as to whether the local lymphocytosis and fibrosis is cause or effect. The clinical cures produced by radium and the roentgen ray in which viable cells still remain in the tissues do not necessarily require the assumption of immunity or a destructive action of the connective tissues. They can be explained as easily by another assumption—that the dense scar tissue immobilizes the cancer cells and the great diminution in blood supply prevents their rapid growth. The cells are put, so to speak, in a plaster cast and cannot be massaged about the body by muscular or other movements. When the tissues are incised and a large amount of blood is furnished the cells as healing takes place, they are then capable of renewed growth and the patient dies of a recurrence. I have seen such examples five or six years after apparent healing had been produced. Unquestionably, the cells are considerably damaged by irradiation. After treating animal tumors with sublethal doses of irradiation and transplanting them to a fresh host where there can be no question of immune reaction, the tumors often do not make their appearance for months, a period that corresponds to years in human beings.

With the exception of the experiments which I have outlined, which are represented on the chart, the results of animal experimentation have not been on the whole consistent and permit no conclusions in regard to primary human tumors.

In other words, the permanent cure of a cancer implies the destruction of all the cells of the growth. The body offers no assistance to therapy, and the many cures obtained in situations in which it is impossible that the cancer cells should all be destroyed must have a mechanical explanation and not one based on the assumption of an immunity reaction.

CONCLUSIONS

1. There is no evidence that the very infrequent spontaneous regressions of human tumors are due to any process of immunization.
2. There is also no evidence that the similar spontaneous disappearance of primary animal tumors is due to any process of immunization.
3. The spontaneous regressions, so often observed in transplanted animal tumors, are an entirely different phenomenon. The tumor is a graft into a healthy host and hence is not perfectly adapted to the soil.
4. *There is no cogent evidence for, and much against,* the conclusion that any process of immunization aids in the therapeutic efficacy of irradiation.
5. Clinical cures can sometimes be obtained by irradiation in situations in which complete tumor cell destruction is impossible but extensive connective tissue sclerosis can be produced, thus locking up any viable cells.
6. The production of absolute permanence of cure by radiation therapy implies that the destruction of the tumor cells must be as complete as must be their removal for effective surgery.

Gastric and Duodenal Ulcer.—The treatment of perforation is becoming standardized. It is agreed on all hands that, whatever is done, the main factor for success is early recognition and early operation. Cases in which operation is performed within twelve hours should not show a higher mortality than 8 per cent., but the mortality advances with giant strides as delay increases. Discussion ranges round two considerations: (1) Whether to do a gastrojejunostomy at the time of the closure of the perforation, and (2) whether to drain. Opinion in England agrees that perforation occurs generally in the chronic ulcer and that in something like 20 per cent. a subsequent operation had to be done for persistence of symptoms of ulcer. Therefore there seems to be a *prima facie* case for some more radical operation than mere closure of the perforation. It must be remembered, however, that some of these perforations are in regions of the stomach where you would not choose gastrojejunostomy as the curative operation, and therefore it is unreasonable to do it just because the ulcer is perforated.—Carson: *Canad. M. A. J.*, September, 1925.

EPITHELIOMA AND THE CHRONIC VARICOSE ULCER *

LEILA CHARLTON KNOX, M.D.
NEW YORK

In recent years, carcinoma of the extremities has found only a small place in the English surgical literature. This is partially explained by the fact that it is often seen in persons generally otherwise incapacitated, that its diagnosis can frequently be made by inspection, and that it generally necessitates a mutilating operation for its cure.

All these facts apply especially to malignant changes that take place in chronic varicose ulcers, and from the surgical standpoint they are, indeed, mere curiosities. Viewed from the standpoint of the cancer research worker, this material assumes an interest of a large human experiment carried out for years on large numbers of persons with only the very infrequent result that a carcinoma appears; and so unusual is it that one hesitates to consider it as a result of the ulceration.

The epitheliomas, more frequently than other types of malignant disease, seem to be incited to growth by long-continued pathologic processes in the tissues. It would be expected, therefore, that ulcers arising on the basis of varicose veins, characterized by years of neglect and subjected over long periods to the various therapeutic agents believed to stimulate epithelial proliferation, and occurring as they do at the age period when other types of carcinoma show a high incidence, would be not infrequently the starting point for malignancy.

That such is not the case, is certain. The theses that have appeared on the subject are valuable because of the carefulness with which the museums and records of the larger clinics have been searched for instances of this disease with such surprisingly meager results. Nobl,[1] who described the different types of benign ulcers in great detail, states that among 4,000 inmates of the almshouse of Lainz, where about 200 crural ulcers were being treated, only one case of malignancy developing from such an ulcer had been seen. Other large municipal hospitals also furnish rare instances, though it is well known that, among the patients in all surgical clinics, varicose ulcers are numerous.

The recent paper of Grosser,[2] who reported 368 cases of carcinoma of the extremities, mentions only six crural or varicose ulcers not mentioned in the older literature.

The records of St. Luke's Hospital furnish only two instances of epitheliomas so associated with varicosities as to make the latter appear an antecedent condition.

The first patient was a very obese Irish woman, aged 65, admitted to the service of Dr. F. S. Mathews in September, 1917. The history disclosed that a small nodule had appeared many years before on the skin over the middle third of the left tibia. A slight trauma resulted in ulceration, and bleeding with progressive growth of the eroded area proceeded for ten years. The ulcer had been treated in clinics three times a week for the past four months.

The patient exhibited many senile changes and was greatly incapacitated by the pain and infection of the ulcer, though she showed no other symptoms or lesions that could be considered secondary to the malignant condition. The calf of the left leg presented a large excavation on the anterior and lateral surfaces, measuring about 14 by 9 cm. and from 3 to 4 cm. deep. The shaft of the tibia was eroded over a considerable area. The skin edges were sharp, not overhanging, but very much indurated. The base was covered with intensely offensive necrotic material, a few fresh granulations and rather flattened warty masses which were not of the fungating type but fairly solid and possessed the grayish translucent quality suggestive of an epithelial growth. The depth and wide extent of the concavity showed a far greater destructive tendency than usually occurs in an ulcer of a benign type.

The leg was amputated at the knee, and the patient made a slow but satisfactory recovery.

Microscopic sections showed that the growth was of the squamous cell type. The greater portion of the base and margins showed extensive differentiation of cell type with many pearls and broken down keratinized areas, the upper layers of the epithelium predominating. There were areas, however, in which the morphology was quite different and only the large hyperchromatic, undifferentiated epithelial cells were seen infiltrating the tissue spaces in parallel columns. If morphology is of significance, this would indicate the aggressive nature of the tumor; certainly the type of growth was exactly the same as is seen in the lip or mouth tumors (Fig. 1).

The part played by the circulatory factor might be questioned here, except that the tissues of the calf presented the unmistakable results of varicosities in the pigmentation of a bronzed or brownish color and the extensive induration and atrophy of skin and subcutaneous tissues alike. This, with a few visibly thickened and dilated veins, made the vascular condition seem a more prominent feature than the patient had regarded it.

Another case illustrates a second and more frequent type of growth, and one in which the hyperplastic character is very noticeable.

A laundress, aged 66, of Swedish descent, admitted to the service of Dr. H. H. M. Lyle in July, 1919, complained of swelling of the right leg as well as of the ulcer. She had had bilateral varicose veins for nineteen years, and the scars of old ulcers were present on the left calf. Ulceration had occurred on the right leg not more than four months previous to admission. The growth had progressed rapidly, and she had been confined to bed for five weeks.

The right calf and ankle showed an unusually widespread fungating growth with sinuous edges, bordered by low papillary masses everted on the skin surface. These nearly covered the base also, although they were intermingled with much gangrenous tissue. The masses were much firmer than granulation tissue, and very vascular. The growth had spread over two thirds of the circumference of the leg in the lower and middle third and over the lateral malleolus. There was a small perforating ulcer over the fifth metatarsal bone. Even in the areas not obviously infected, the tissues of the foot and ankle were extremely edematous, and the peroneal and tendons of the anterior muscle group were exposed and partially atrophied (Fig. 2).

The extremity was amputated in the middle third of the thigh, the wound healed, and the patient has remained well for five years.

Microscopic examination showed (Fig. 3) that the papillary projections are composed of a highly differentiated type of squamous cell epithelioma.

LITERATURE

Slight inspection of the literature will at once show that it is difficult to separate these carcinomas from those originating in other chronic inflammatory processes. In many of the older accounts, also, no attempt is made to exclude contributory causes, such as syphilis or other dermatologic lesions. No classification can, therefore, be considered wholly accurate even though most of the "scar carcinomas" and "fistula carcinomas" can be excluded.

The former are not numerous, the reported cases numbering less than fifty if we exclude the lupus scars. They are epitheliomas usually arising on the extremities, but, like other epitheliomas, are more numerous on the face. They have followed, usually after many years, the healing of a single lacerated wound or a burn, though in rare instances other forms of trauma, as a dog-bite or freezing, have preceded the scar and been regarded as the cause of it by the patient. A case which is illustrative of the group is that of Volkmann.[3] The patient was a man who sustained a lacerated wound of the calf at the age of 27. This healed without prolonged suppuration or bone necrosis, but the scar broke down thirty-five years afterward and the resulting ulcer grew rapidly with every indication of malignancy. Such a condition has, if syphilitic, as a few of these may be, the disturbance in its vascular supply, possibly not much different from that which obtains in the region of a varicose ulcer. This might be considered as evidence that the altered and deficient circulation cannot be regarded as an important factor in developing malignancy, and, in fact, it might well be thought an inhibiting influence.

The fistula carcinomas, of which about the same number, forty-five, have been described, have also developed most frequently on the calf or ankle. These patients have practically all suffered from early osteomyelitis, which later became chronic and eventually gave rise to an ulcer of considerable size. In many cases the infection dates from childhood, and the chronic sinuses like the crural ulcers may or may not have healed at times; but finally tumor tissue has appeared, in the fistulous tract, in the ulcer, or in the scar tissue surrounding them. The malignant process has, of course, added to the destructive bone lesion so that the end-results may be indistinguishable from the varicose epitheliomas, which also secondarily absorb and erode bone. Either type not infrequently has caused a spontaneous fracture.

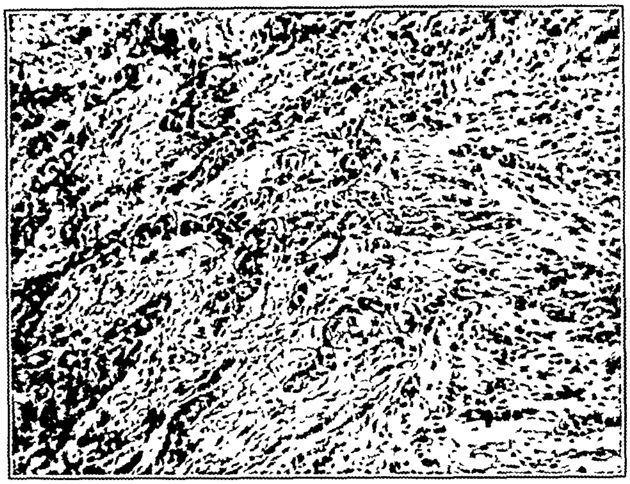

Fig. 1 (Case 1).—Margin of ulcer, showing relatively undifferentiated type of cell and infiltrating character of growth.

Of the third class, or varicose carcinomas, about fifty cases have been described, while six others have been referred to in the literature, or described orally in personal communications, exclusive of those in persons known to be syphilitic. It is unnecessary to give detailed accounts of all the reported cases, as the clinical histories are remarkably similar; but a survey of the literature is of sufficient interest for a brief summary.

The most comprehensive discussion is the monograph of Volkmann,[3] who, in 1889, collected the cases of this type as well as the other carcinomas located on the extremities. Twenty-four were associated with varicose ulcers.

Gant,[4] in the same year, described another case seen at the Royal Free Hospital in London, although this, like a few others, may have arisen from a cutaneous growth which became infected and ulcerated. In any case, the ulcer remained nearly stationary for a long period before there was any evidence of malignancy.

Michael,[5] in 1890, reviewed Volkmann's material and added reports of twenty-six cases of carcinoma of the extremities seen in the Tübingen clinic, eight of them associated with crural ulcers.

Druckenmuller,[6] in 1895, reviewed Michael's cases, and contributed accounts of three more cases, one being only the third on record in which bilateral crural ulcers both formed the starting point for carcinomas. Druckenmuller's case occurred in a woman, aged 58, who had had ulcers on both legs since 25 years of age. Both had healed at times, only to break down again, but for the past year there had been rapid growth in each. One was 9 cm. in diameter, the other twice its size, and both showed fungating masses on base and edges.

Volkmann's patient was a man, aged 51, who also had had crural ulcers for twenty-five years with rapid growth in each for six months. There were large cauliflower-like masses on the outer sides of the ulcers. Local excisions were done, with a rapid recurrence on one side.

The third bilateral case is a recent one reported by Grosser from the Urban Hospital. The patient had bilateral ulcers for many years, one eventually becoming carcinomatous; the leg was amputated, but seven years afterward the patient returned with the same condition on the other leg.

These three cases are of interest for, like other multiple growths, they suggest the important question of the part that is played by individual predisposition.

Nobl describes with illustrations, three cases which he had seen and which depict three slightly different forms that this type of growth may assume.

Neumann[7] and Woolsey[8] each briefly describe one specimen, and DaCosta[9] adds two more.

A more recent discussion is that of Gottheil,[10] who saw only three specimens in his experience at the Metropolitan Hospital, New York, where, of course, a large number of dermatologic lesions was constantly observed. He believes that the chronic dermatitis rather than the vascular condition should be regarded as the important preceding lesion, and thinks that whatever alteration there may be in the circulation is merely a contributory factor to a process that begins in exactly the same manner as do the epitheliomas following syphilis, tuberculosis and other chronic skin diseases. In discussing Gottheil's paper, Hazen described a case seen by him in which the varicose ulcer had existed for fifteen years, and simultaneously with the onset of an acute eczema in the surrounding skin the malignant process appeared. Agreeing with Gottheil, he seems to feel that the cutaneous inflammation gave origin to the epithelioma.

Heidingsfeld, in discussing the same paper, mentions two cases which he saw at the Cincinnati General Hospital, and I am indebted to the following for oral accounts of three more: Dr. John Douglas, one case at Bellevue Hospital, New York; Dr. G. L. Rohdenburg, one case at the Lenox Hill Hospital, New York, and Dr. Lyman Richards, one case at the Turkish Hospital, Smyrna.

Grosser, extending Volkmann's compilation, describes six more cases of crural ulcers with epithelioma. All his patients had had ulcers for many years, and a woman, aged 34, showed involvement of inguinal nodes by the tumors.

De Jong, Meyer and Martineau[11] described a varicose carcinoma of the leg treated for eight years with a preparation containing tar. The patient was a man, aged 85, seen in 1916 with varicose eczema of the leg. To allay itching, the tar preparation was applied and so successfully that the patient continued the applications until 1924, when he was again seen, this time with a brown dermatitis, edema of the leg, and an ulcer with ragged, overhanging edges. A biopsy showed that the fleshy portions consisted of squamous cell epithelioma. It will be questioned whether the application of the tar preparation was effective in transforming the inflammatory condition into a malignant one, but in view of the extensive experimental work on tar carcinoma in mice, it is of considerable interest.

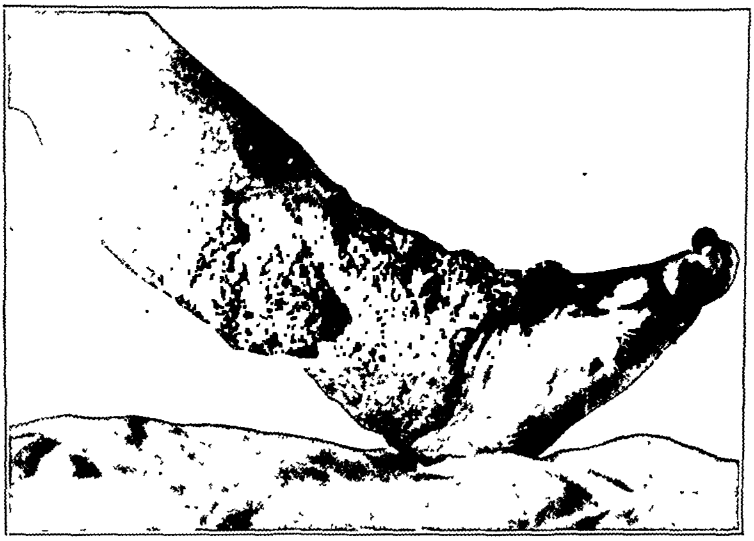

Fig. 2 (Case 2).—Extensive ulceration and papillary type of growth covering the entire surface.

Summarizing these cases as a group, we find that about the same number have occurred in men as in women, a fact not usually regarded as true of the benign varicose ulcers. Of the fifty-nine cases, the sex is stated in fifty-three. Of these, twenty-eight, or 52 per cent., were in men, and twenty-five, or 48 per cent., were in women.

The ages are given in forty-nine cases: from 30 to 39 years, three cases; 40 to 49, thirteen; 50 to 59, fourteen; 60 to 69, seventeen; 70 to 79, two. This shows plainly that the incidence between the ages of 40 and 60 is practically constant, and that it is virtually the only age period in which the condition appears.

The duration of the ulcer prior to the tumor growth is of even more interest. In nearly all instances they are said to have existed "for many years." In the twenty-eight cases in which the term is stated, the average is 21 years, with a maximum of 40 and a minimum of 10. The onset of the malignant process has nearly always been noted by the patient himself, either because of increasing pain or because of rapid growth of the exuberant cauliflower-like masses, or, in a smaller number of cases, by the rapid extension of the crater. The time elapsing between this change and the appearance of the patient in the hospital has generally been about a year, fifteen cases giving an average of fourteen months.

The diagnosis is fairly certain when these solid vascular outgrowths appear on the formerly smooth, indolent base, and the edges assume a fungating character. The warty masses are solid and fleshy, and possess a cellular translucent appearance, not seen in the small, soft granulations that are occasionally present in many chronic ulcers.

There are two distinct morphologic types assumed by these growths. In the one, which is more common, the hyperplastic tendency dominates the picture. The ulcer may be shallow, as in the second St. Luke's case, the papillary masses small and numerous, fringing the edges and base uniformly. The second type, which is rarer, shows the destructive and ulcerative aspects of the malignant process, the growth being more concealed under the margins, which it infiltrates and undermines. The warty nodules are larger and firmer than in the first type, and may be found only on the base. Not infrequently, however, the papillary growth appears in only a part of the ulcer, as at one side. In such a case, it has not been determined whether the entire circumference is carcinomatous.

Amputation has been performed in the majority of cases, generally without observed recurrences for a period of several months or years; but to attempt to draw exact conclusions regarding the outcome of these cases as a group is impossible, as relatively few have been followed for more than a year. Several, however, have been free from any recurrence or metastasis for three or four years, in one case, fourteen years; therefore complete cures are not unlikely. The mortality from septicemia was considerable in the earlier cases.

Involvement of the inguinal nodes is neither constant nor early. They have usually not been resected at the time of operation unless definitely carcinomatous. In about 16 per cent. of the cases, a subsequent metastasis has appeared in the inguinal or retroperitoneal nodes. At least three patients have died from pelvic or other extensive metastases, and two of these from hemorrhage due to erosion of the femoral or popliteal artery by such a recurrence.

COMMENT

Gottheil's assertion that the varicose ulcer is a misnomer is one that may find more dermatologic than surgical support. Of course, there is no doubt that the two lesions are almost invariably found together, and both may contribute to the end-product. It is noteworthy, however, that only a few of the dermatoses have directly given rise to epitheliomas either in the lower extremity or on the hands and face, where both conditions are much more frequent.

---

[11] De Jong, Meyer and Martineau: Bull. du cancer **13**: 326, 1924.

Epithelioma arising in lupus scars is generally recognized as a fairly frequent occurrence, and may occur in either skin or mucous membrane. It is estimated by Zweifel-Payr[12] that 2 per cent. of the lesions of lupus vulgaris eventually show epithelioma. Only rarely does malignancy occur in an active lupus erythematodes. Ashihara,[13] who collected reports of about 300 cases of all types of the latter epitheliomas, pointed out that, in several larger series of cases reported from different sources, each showed the incidence of epithelioma arising from old tuberculous scars to be more than twice as frequent as those appearing during the course of a florid lupus; that is, 70 per cent. of the cases were of the former type. For this reason the dermatologists have regarded most of the cases only as scar carcinomas and do not believe that the tubercle tissue has any especial significance. Orth, however, in studying the problem from the point of view of relative tissue resistance, questions whether the effect of the tuberculous granulation tissue is not to remove in some special way the normal controlling mechanism which causes epithelial cells to cohere.

The fact remains that epithelioma of the skin is much more frequent following lupus than any other chronic skin disease.

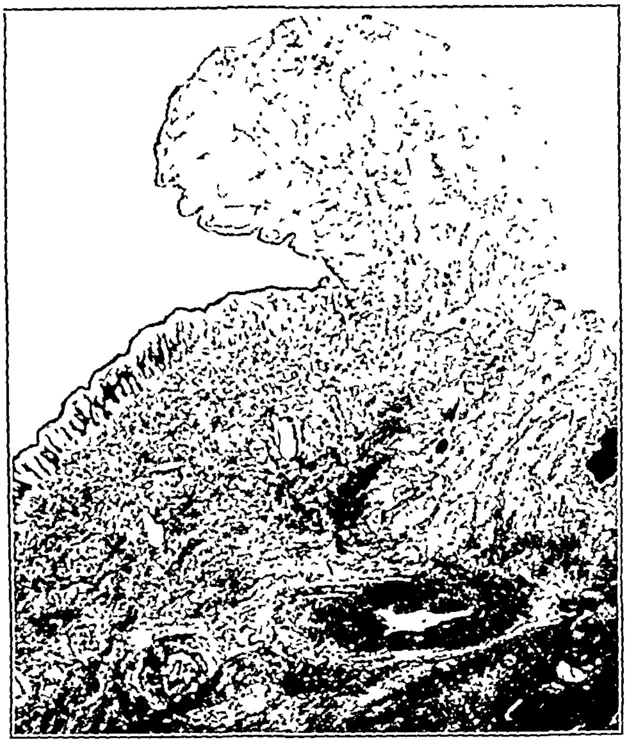

Fig. 3 (Case 2).—Papillary mass, showing differentiated type of growth; low power.

Psoriasis and syphilis are likewise possible, but unusual, predisposing types of inflammation. Roentgen-ray epithelioma is relatively common. Chronic eczema is an extremely common condition, and the inflammation extends over long periods, but it is not considered a causative agent except in the skin over the tibia. It is apparently not necessarily keratoses in which epithelial hyperplasia is a factor from the beginning which form the basis for the malignant process. It seems, therefore, that these two factors, either an epithelial hyperplasia or some specific etiologic agent, must be added to the exudation caused by irritation.

Cancer research has been directed by this observation, and successful experimental carcinomas have been produced by special agents believed to have excited spontaneous carcinomas to growth. Hot tar, which has long been believed occasionally to cause multiple human epitheliomas, as in the case described by Voigt,[14] has been used successfully on the skin of white mice and the rabbit's ear; on the other hand, the skin of albino rats is not sensitive to tar painting. The duration of the irritation is of the first importance, illustrating again the fact that the irritation alone is only one factor, and that we are largely in ignorance of the others. Irritation epitheliomas cannot be induced in six months, whereas they may be in twice that time in animals. This may be analogous to the fact that these varicose ulcers have been usually present from fifteen to twenty years before a malignant change has occurred.

Fibiger[15] has produced a few epitheliomas in the stomach of the mouse and of the rat by irritation of *Spirotera* in these tissues. This irritation also must be continued for a considerable part of the animal's life before any such growth occurs.

. In these experiments, as in the epitheliomas arising in the mouth and lips in human beings on an ulcerative or irritative basis, there is presumably a normal blood supply—the factor that is absent in these varicose carcinomas. There is no doubt that, whatever the other circumstances, a carcinoma will grow faster, when once formed, if the blood supply is adequate. To explain the rarity of these lesions, we must again take refuge behind that unexplained but obviously important question of local and individual predisposition. If the geneticists are right and cancer is due to susceptibility and irritation, it remains difficult to understand why, with so many patients exposed to this irritative condition for so many years, the hereditary tendency should be so ineffective a factor and so few epitheliomas develop. The hereditary predisposition would then be assumed to be local—a wholly impossible conception for the human race. That the epithelium of the lower extremities has always been an infrequent site for epitheliomas, despite the irritation to which they are subjected, is admitted. The response to irritation of any type in this locality is regularly in the direction of a protective reaction or benign hyperplasia, as in the callosities that occur on the feet. Epithelioma developing from such callosities is not unknown, but it is extremely rare. It is an astonishing phenomenon that, among only fifty-four leg carcinomas, three should be bilateral, and can be explained at present only on the basis of individual predisposition.

CONCLUSIONS

There are accurate reportes of only fifty-nine epitheliomas arising in chronic varicose crural ulcers.

The number of the reported cases is about the same as those arising in scars and fistulas.

[15] Fibiger: J. Cancer Res. 9: 367, 1919

These occur almost exclusively between the ages of 40 and 60, run a slower course than other squamous cell epitheliomas, and probably lead to metastasis later. They are in no sense benign.

It is probable that chronic dermatitis more than the varicosities and altered blood supply alone incites the condition.

These tumors seldom arise until an ulcer has been present for at least fifteen years.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. WOOD AND KNOX

Dr. Francis Carter Wood, New York: I should like to say a word about Dr. Knox's paper from the general point of view of causation of cancer. She has hinted in regard to the question of hereditary susceptibility. There is no question that there are families in which a large proportion of the members die of cancer, and there are other families in which no one dies of cancer, even though they all reach cancer age. Of course, the animal experimentation done by Maude Slye in Chicago and by Bullock and Curtis in my laboratory have definitely proved that in animals a susceptibility to cancer is transmissible. Of that there is no question. The breeding experiments, however, are so complicated and take so long that if they were applied to human beings, it would mean that for the last 5,000 years both parents of these unfortunate human beings would have had to have cancer. That is a concentration of breeding which cannot occur in the human race. So the facts of the high incidence of cancer in these experimental studies cannot be applied in full value to human beings. The sixty cases that Dr. Knox has with great labor been able to collect from the literature represent an infinitesimal fraction of the population of that age, and during that time thousands of persons of the same age were dying of cancer in other areas. Must we assume, then, that there are local susceptibilities in the body, that the skin of the legs does not carry an hereditary susceptibility and that that of the tongue and lips does, or must it be a question of the potency of the irritant in the different areas? The paper raises that very interesting question, and it will be necessary to collect a large amount of material to answer it. Cancer of the tongue and cancer of the lip of course kill four or five thousand persons annually in the United States, and probably not more than one or two die of leg ulcers, perhaps not that many. What is the cause of this difference? We are at present unable to answer that question.

Dr. J. Shelton Horsley, Richmond, Va.: There is no part of the body on which irritation is so common as on the palmar surfaces of the fingers, and yet I have never seen a cancer develop there. On the other hand, at points of irritation in the mouth, cancer is common. It would seem possible that the tissue on the palms of the hands and the soles of the feet was stabilized in evolutionary times to such an extent that it acquired resistance, whereas other tissues have not acquired a resistance to new traumas, such as the use of tobacco. That, of course, is just a theory, but it is one way of explaining the very obvious difference in the reaction to irritation in the different parts of the body. Basal cell cancer presents an interesting problem. It practically never metastasizes. It varies greatly in morphology and structure, possibly because it comes from the deep layers of the epidermis and is more closely akin to the sweat and sebaceous glands and the hair follicles than spinous cell cancer, and, being closely akin, it may revert more easily to adenomatous structure. At any rate, a very distinct glandular structure sometimes occurs in basal cell cancer. In intractable basal cell cancer, after excising the cancer I have transplanted a flap from a distance with the idea that there is some natural resistance of tissues at a distance to basal cell cancer which prevents metastasis. If basal cell cancer does not metastasize, there must be a reason for it. It grows in a rather regular zone of infiltration, and it seems as if it must elaborate some material which breaks down the resistance of the normal tissue to the advance of the basal cancer. On the other hand, spinous cell cancer of the more malignant type and arising in the same region is transported and readily grows in lymph nodes. In ten cases treated on this theory, there have been five recurrences and five have not recurred. Several are of very recent date. One of the patients died from angina three years after this operation, and there was apparently no recurrence of the cancer after the transplantation of a distant flap. Recurrences in five cases were not in immediate contact with the flap nor in the flap, but in tissue a little distant from the flap, and never any closer than 0.5 cm. Sometimes they would grow to the margin of the flap and there would stop. Whether sooner or later the resistance of the flap will be broken down and the cancer involve the flap I do not know, but this has not occurred so far. In a case of spinous cell cancer, quite advanced, in which an extensive operation was done, including excision of the external ear and the tissues in the temporal region, I transplanted from the back a flap in stages so as to develop the nutrition. This was done simply for cosmetic purposes and not with any idea of cure. There was a recurrence of the cancer from the epithelial tissue lining the canal of the ear, which had not probably been thoroughly removed. That occurred about the middle of the flap and readily grew through the flap. This case may be said to have acted as a kind of control.

Dr. Isaac Levin, New York: I wish to subscribe to the statements of Dr. Wood. All we can do for a patient with an advanced cancer is to prolong his life for a while. It is interesting to note in connection with the experimental work presented by Wood that it is much more difficult in the human being to influence therapeutically a metastatic tumor than the primary condition. Surgical excision, radium and even cauterization may destroy a carcinoma of the lip, but it is extremely difficult to influence the metastases in the lymph nodes of the neck. The inoculable tumors with which Wood experimented represent in reality experimental metastases. It is difficult to offer correct analytic deductions in cancer research, since the fundamental premise, the etiology of the disease, is unknown. The investigation of Dr. Knox represents the most efficient method for the study of both the etiology and therapy of cancer. Wood uses thousands of mice and rats in experimental cancer research, and the life cycle of these animals is only two years. How much more difficult is the problem in man, in whom the life cycle is seventy years. In order to advance our knowledge in human cancer, thousands of cases have to be studied throughout the world and the results checked up in a common clearing house. I look forward to the day when every municipality in the world will maintain an institution for clinical cancer research and when all the investigators will have opportunity to compare calmly and carefully one another's results.

Dr. E. A. Case, Philadelphia: Dr. Wood has so thoroughly covered the question of immunity that there is very little to say, but I would just like to add this: I think it is the experience of every efficient pathologist who has had an opportunity to examine tissues that have been irradiated some time previously, in which a so-called clinical cure has been established, to find tucked away, carefully covered up by connective tissue, these little areas of viable cancer cells, for one occasionally finds in them evidence of proliferation. I recall one case in which practically the entire tumor was destroyed, and yet down deep in the tissues we found these cancer cells. Clinical evidence in addition to pathologic evidence has shown us that in so-called clinical cures not only recurrences but also metastases occur as late as ten or twenty years afterward. I recall one case that is quite classical in our city of a sarcoma which eventually destroyed the man's life twenty years after he had his eye removed.

Dr. A. J. Carlson, Chicago: Dr. Wood's paper, as well as the paper of Dr. Knox, seems to show that it is entirely possible to do the same accurate observation to demand the same scientific control, and use the same kind of mental processes in clinical work as in so-called laboratory research. If that is possible, why don't we insist on it; why don't we apply it universally? There are not kinds of facts, so-called laboratory facts and clinical facts. If they are facts, they are facts, and they are established in the same way. I am familiar with Dr. Slye's work, and I have waited for this type of experiments on the hereditary cancer material. I should like to know whether these strains with the high incidence of spontaneous tumors are more susceptible to the various agents that induce so-called experimental tumors.

Dr. Francis Carter Wood, New York: The possibility of the locking up of cancer cells in the tissue for long periods is familiar to all students of the disease. It may occur after radiation treatment, or after radical removal of a tumor. One interesting example was a patient with epithelioma of the lip who had been treated thirteen years previously with radium. A recurrence took place at exactly the same site as the primary tumor and with exactly the same morphology. The assumption that a new tumor had occurred at the same place is therefore unwarrantable. In other words, for thirteen years cancer cells remained in abeyance in the scar. There are many other examples of late recurrence in scars produced by treating cancer with caustic paste or after freezing squamous cell epitheliomas of the face with carbon dioxid snow; also I have seen many scar recurrences after radical mastectomy five and ten years after the operation. The facts of which Dr. Carlson spoke are well illustrated by certain experiments on rats at the Crocker Laboratory. By infesting the animals with a parasite which forms a cyst in the liver, we have been able to find those whose livers were susceptible to irritation by the production of a sarcoma. This in the ordinary run of laboratory rats is about one in 500. By breeding together those rats which proved to be susceptible to the development of a tumor, we have obtained a susceptible strain whose livers have an enormous susceptibility to the irritation of a parasite. Sometimes we get a 100 per cent. susceptibility in a litter of animals. This shows that by selective breeding the liability of an organ to develop cancer under the action of a definite stimulus can be concentrated. In other words, it demonstrates in rats what has been known for forty years in man, that a congenital tissue susceptibility is transmissible. The answer to Dr. Carlson's question brings out a theory tested by another experiment: The skin of the ordinary white rat does not react to tar painting by the production of cancer, though the skin of mice is exceedingly sensitive. We thought that possibly the strain of rats with highly susceptible livers might also have skins which had become susceptible, but on painting a large number of animals with tar no skin susceptibility was found. Thus the susceptibility was entirely for a single tissue—the connective-tissue structures of the liver.

Gland Extracts Mostly Devoid of Action.—We meet with advertisements of extracts of blood (hemoglobin), bone marrow, muscle, spinal cord, brain, lymph gland, spleen, prostate, ovary, testis, mammary gland, duodenum, pancreas, liver (bile), placenta, gastric mucous membrane and kidney, to say nothing of the adrenal bodies (both cortex and medulla, and the whole gland); thyroids, parathyroids, pituitary body (both anterior and posterior lobes and the whole organ), the pineal body, and the corpus luteum. Various mixtures of these extracts are also put on the market and are presumably sold, as e. g., ovary and mammary gland extracts, mixtures of extracts of lymph gland, testis, spinal cord, and brain; combinations of thyroid and pituitary substances, and of thyroid adrenal extracts; such combinations as "polyglandin," a mixture of thyroid, parathyroid, ovary, testis and pituitary extracts. Several of these combinations are sold with or without the addition of the drugs, under various fanciful names, as "virtilogen," "mammagen," "ferovarim," etc. Now in the case of the great majority (in fact, in all except one) of these preparations there is no evidence that any effects whatever are produced when they are given in the ordinary way by the mouth, unless they are given in such quantities as to serve as foods.—Vincent, Swale: *Proc. Royal Soc. Med.* **18**:30 (June) 1925.

REVERSE PERISTALSIS IN THE BOWEL, A PRECURSOR OF VOMITING *

WALTER C. ALVAREZ, M.D.
SAN FRANCISCO

It is remarkable how little has been written about the behavior of the bowel during the act of vomiting. One can read for days about the rôles played by the medulla, the vagi, the pharyngeal sensitive points, the esophagus, the abdominal muscles and the stomach, but only here and there will one find a brief reference to the bowel. Significant of this state of affairs is the fact that in Hatcher's [1] summary of our knowledge about vomiting I can find no word about the bowel.

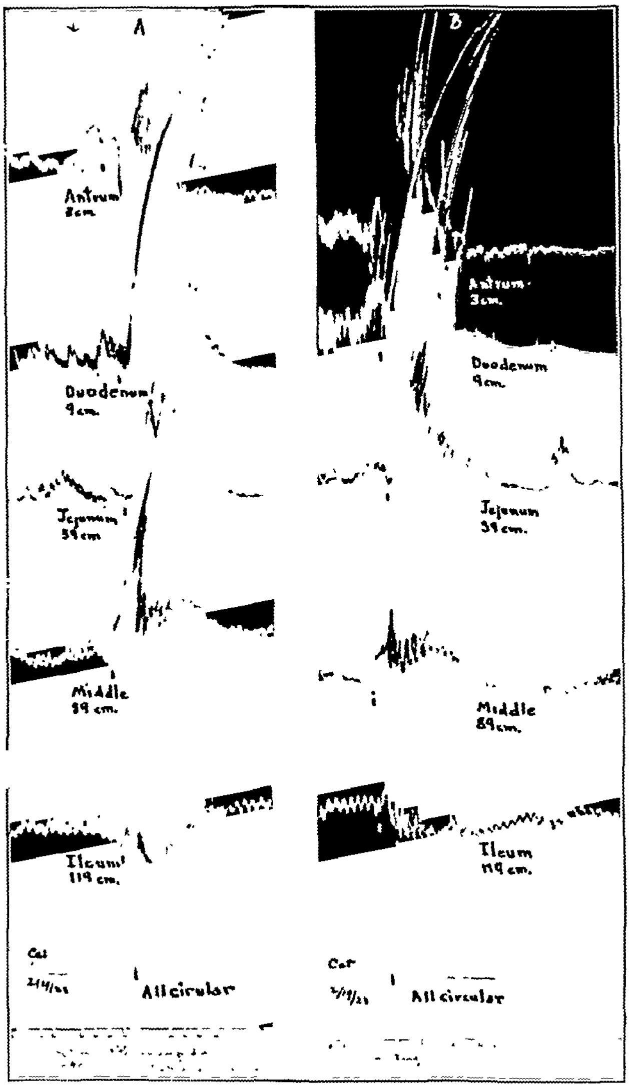

Fig. 1.—Records depicting waves of reverse persitalsis in the cat's bowel preceding vomiting.

Certainly there must be some reason for this blind spot in our vision, and the most probable one is that we have never been able to record exactly what is going on in the various parts of the bowel at the same time. Another reason is that in our lay youth we become so used to thinking of the stomach as the organ of digestion that later, when we should know better, we sometimes forget that there is such a thing as a bowel. Another trouble lately is that our attention has been diverted from the abdomen to the vomiting center of the brain, largely on account of the experiments of Eggleston and Hatcher[2] which showed that an animal can retch even when its digestive tract from cardia to anus has been removed.

---

* From the George Williams Hooper Foundation for Medical Research, University of California Medical School.

[1] Hatcher, R. A.: Physiol. Rev. **4**: 479 (July) 1924.

Although there can be no question about the importance of the nervous mechanism which Hatcher and his associates have demonstrated, it seems to me that the possibility still remains that certain types of vomiting either originate in reverse peristalsis in the bowel or else are associated with it. I see no reason why the emptying of the intestinal contents into the stomach or even the mere reversal of peristalsis in the bowel should not be one of the many factors that we know can call forth those coordinated activities of stomach, diaphragm, abdominal muscles and esophagus which we call vomiting.

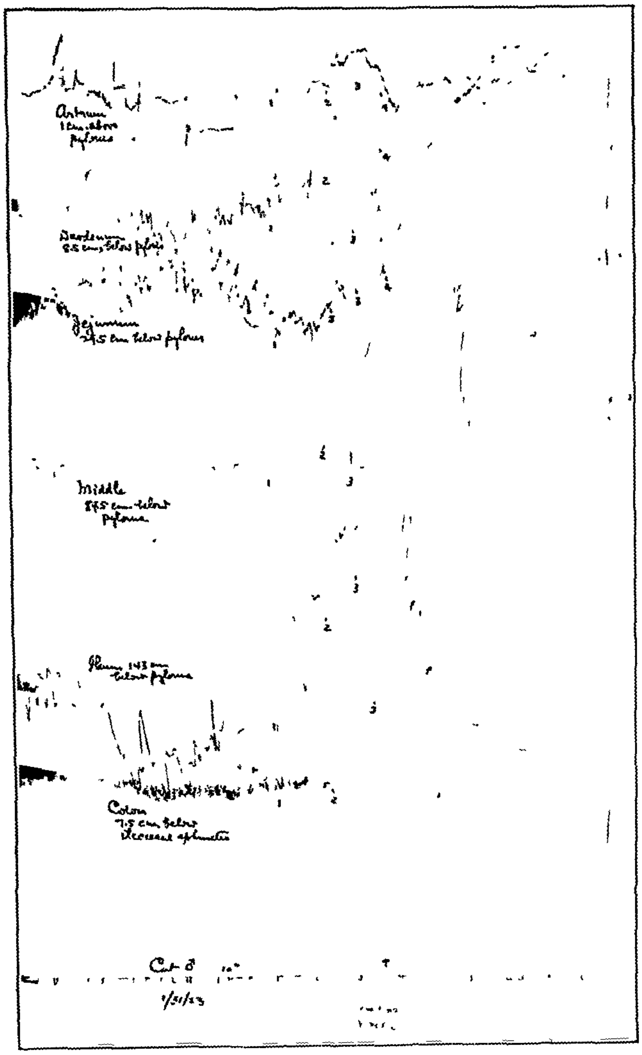

Fig. 2.—Record depicting a combination of tonus contractions and a reverse wave associated with vomiting.

We know also from the experiments of several workers on different animals that the stomach can empty itself orad without any help from the abdominal press; and we see much the same thing in infants and some adults when large amounts of material are regurgitated from the stomach without apparent effort. Actually, in these cases it is often hard to say whether we are dealing with pure regurgitation or real vomiting, because they shade so, one into the other.

Clinicians and surgeons know also that men and women with acute appendicitis or other irritating or obstructive lesions in the bowel will sometimes vomit large amounts of fluid a few minutes after their stomachs have been washed clean. This fluid will often be bile-stained or tainted with feces or enema material, showing clearly that it has come from the bowel.

The strange inability of many writers to conceive of an active reversal of peristalsis in the bowel is shown again by their rather thoughtless statements to the effect that this regurgitation is due to suction by the stomach. Just how this suction is accomplished by soft collapsible tubes that cannot actively dilate is not specified.

Twelve years ago, when I first began the study of the intestine with the animal opened under salt solution, I saw on several occasions waves of reverse peristalsis. I was watching the intestines of cats under urethane anesthesia, with their lower cords pithed, the rectum tied, and the colon filled with pea-soup or soapy water. After an hour or more the colon would usually become very active in its efforts to rid itself of its contents, and occasionally then a wave carrying some of the soapy water would travel rapidly up to the jejunum or even to the stomach.

On many occasions also I was struck by the fact that gastric regurgitation or actual vomiting had been preceded by a short period during which there was great activity in the small bowel. On searching through the literature, I found that some of the older writers on vomiting had observed this phenomenon. I observed it also in a man with a jejunal fistula. He happened to vomit one day while I had a balloon in his bowel, and it was very evident from the record that a marked increase in the activity and tone of the jejunum had, for about two minutes, preceded the retching. Actual reverse transport of material was shown by the fact that he vomited the egg-milk mixture that had been given him through the fistula.

Two years ago when Miss Mahoney and I[3] began to get good records from several parts of the cat's bowel at one time, we were able, not only to see a number of reverse rushes traveling up the bowel, but also to record them graphically. Two typical records are shown in Figure 1. Unfortunately, details of the gastric record were obscured by the retching movements. In Figure 1 *A* it will be noted that vomiting was apparently initiated by a pinching of the fundus of the stomach. The effect of this pinch was registered immediately from one end of the tract to the other, and fourteen seconds later a small reverse rush passed the recorder on the ileum 119 cm. from the pylorus. It seemed steadily to gather force as it went, and it passed the upper duodenum, 9 cm. from the pylorus, six or seven seconds later. Its rate of travel was therefore from 16 to 18 cm. per second.

Figure 2 shows what happened when the animal regurgitated so much that, for a moment, we thought that it was really vomiting. The record shows, however, that there were no retching movements. A rise in tone began practically simultaneously in "middle" and "ileum." A wave then traveled steadily from the ileum to the duodenum but did not seem to reach the stomach. At 2, there was another rise in tone, which was almost synchronous from colon to stomach. The only exception was that the duodenum responded with a drop. At 4, the animal regurgitated, and the tone of the gastric antrum fell. The interesting feature here is the reverse wave traveling up the bowel, associated with peculiar rises in tone which appear at the same time in almost all parts of the tract. I have commented before on a similar phenomenon in the stomach where systoles are sometimes associated with waves traveling up and down. Attention is called also to the marked drop in tone that occurred in the ileum two minutes before the rise began, and 4.5 minutes before the animal regurgitated.

---

[3] Alvarez, W. C., and Mahoney, L. J.: Am. J. Physiol. **69**: 212 (July) 1924.

Figure 3 shows again how long a time the intestine may spend in preparing for a vomiting spell. We note the rise in tone of the duodenum and jejunum at *A*, three minutes before the animal began to retch. A second disturbance, which appeared throughout the tract at 1, was most marked at the lower end. It traveled upward so slowly that it reached the stomach after vomiting had begun.

Dr. Zimmermann and I have recently obtained records from a rabbit showing an orad progression of powerful contractions. Unfortunately, we could not see clearly what was going on, so we cannot say definitely that it was a reverse rush wave, but that is the logical inference from the records.

COMMENT

The fact that a number of these records show a temporary depression before the sudden rise which marks the advancing wave, brings up the question of Bayliss and Starling's law. Such a depression is assumed by most writers to mean temporary inhibition; but when we watch very carefully we see that some, or perhaps all of it, can be due to distention by the column of intestinal contents, which is pushed ahead by the contraction-wave much as a train of cars is pushed by an engine. We cannot deny that there may be an element of inhibition sometimes present, but neither can we assert that it is present until we can exclude this element of distention.

If we should decide that at least a part of this drop in the record is due to inhibition, we would be faced by a difficulty in that we could no longer follow those who say that the myenteric reflex is brought about by a certain arrangement of neurones in Auerbach's plexus. Such a structure could hardly be reversed so suddenly. Furthermore, if the myenteric reflex will work equally well both ways, up and down the bowel, we can no longer ascribe to it the faculty of maintaining the caudad direction of peristalsis.

We have some difficulties also in reconciling our findings with the gradient theory. According to that theory, waves travel down the bowel simply because there is a gradation in metabolic rate, tone, rhythmicity and sensitiveness to distention or to the presence of food, from the duodenum to the ileum. Material moves from the more active, irritable regions to less active and less irritable ones. Although this gradient is built into the structure of the bowel, it can probably be upset quite easily by agencies which either increase the activity of the lower end or lower that of the upper end. Sometimes we can show a flattening or reversal of the rhythmic gradient in sick animals or in animals that have been vomiting or refusing food, but there are puzzling exceptions. We find also that distempered dogs will have a decided flattening or reversal of the gradient of latent period without much change in the rhythmic gradient.

Flattened rhythmic gradients were actually found in a number of the regurgitating cats observed during this study, but it happens that the particular animals whose records are shown here had a good gradation running from 18 per minute in the duodenum to 10 in the ileum. The rabbit with signs of reverse peristalsis had no rhythmic gradient below the upper jejunum. This was due to a lowering of the normal rate in the duodenum and jejunum and a rise in the rate of the lower ileum. Just why this occurred we do not know, as the animal seemed to be healthy.

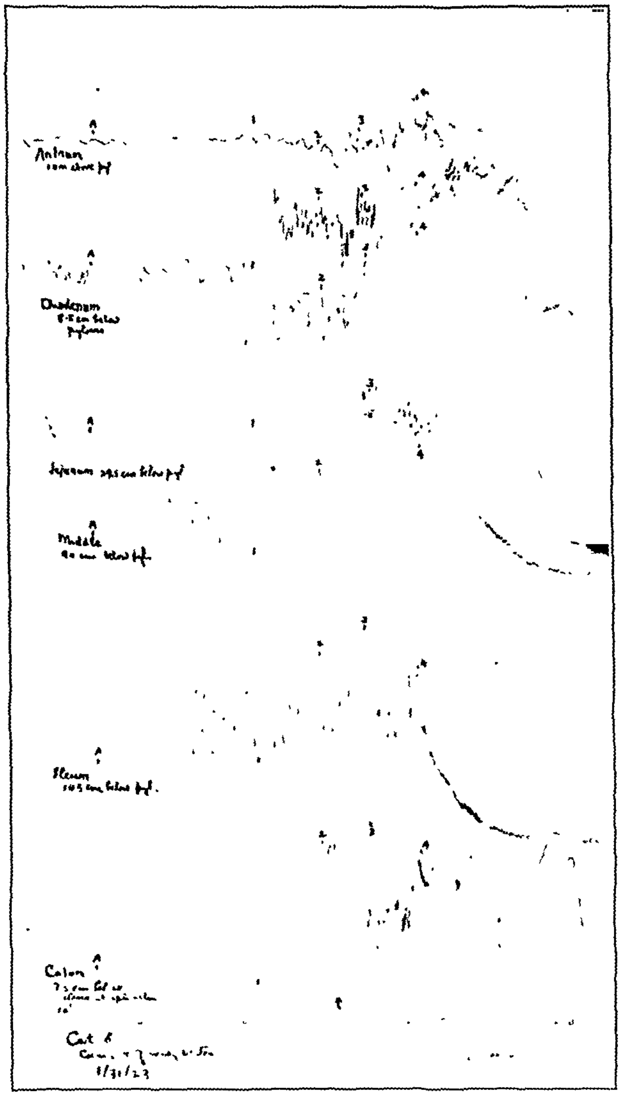

Fig. 3.—Record showing how long the bowel may take in preparing for vomiting. In this case the reverse wave reached the stomach after vomiting had started.

Studies on scores of animals during the last twelve years have given me the impression that the rhythmic gradient is not changed much by acute processes such as sudden intestinal obstructions. It seems to be flattened or reversed only if the animal is sick for some time. Reverse peristalsis may take place in animals with good gradients if the tone or irritability of the lower end of the tract is raised sufficiently. Once the wave is started orad it can travel even against the gradient, because the material that is pushed ahead is constantly giving rise to new contractions. Regurgitation caudad cannot take place because, as we may see from the records, the bowel remains tonically contracted for a minute or two after the wave has passed. By that time, the head of the onrushing column is far away. This mechanism has been discussed more fully in another article on peristaltic rush.[3]

Naturally, when there are powerful contractions and marked rises in tone in the lower ileum, waves may travel out in both directions from the irritable point, and we know that diarrhea actually is often associated with vomiting.

It is well known, of course, that regurgitation from the duodenum into the stomach is a normal happening at certain stages of digestion.

There would seem to be no question, then, that vomiting is often preceded by an increase in the activity of the bowel, by a rise in tone there, and sometimes by a wave of reverse peristalsis. Unfortunately, we cannot yet say just what bearing these changes have on the events that follow. They may lead up to the vomiting act and may be partly or largely responsible for it, or they may be but a part of the vomiting complex brought on by influences coming from the center in the medulla.

As I[4] pointed out several years ago, it is suggestive that nausea is felt by many people in ascending waves which may perhaps correspond to actual waves on the bowel. Many persons are distressed the minute their hearts develop abnormal types of rhythm, and I see no reason why abnormal types of peristalsis should not similarly register themselves in some way on our consciousness.

Just as this paper was being sent off, the article of Keeton[5] appeared in which he reports the production of nausea in human subjects by the injection of various substances into the duodenum. Some of his findings suggest that, with the waves of nausea, the bulb on the end of the tube was returned to the stomach. Ivy and Vloedman[6] have recently observed the same thing.

SUMMARY

Writers on vomiting have ignored the part played in the act by the bowel.

The regurgitation of intestinal contents into the stomach during or preceding the act of vomiting must be a common occurrence, judging from clinical observation.

Records made simultaneously from several regions of the bowels of cats, opened under a warm bath of salt solution, show that vomiting or regurgitation of gastric contents is almost always preceded by an increase in the tone and activity of the small intestine. Actual waves of reverse peristalsis have also been observed and recorded.

An increase in the tone and activity of the jejunum beginning two and one half minutes before the onset of vomiting was recorded graphically in a man with a jejunal fistula. Food put into the fistula was vomited.

Depressions which suggest a preliminary inhibition, but which may be due only to distention by the oncoming intestinal contents, are observed in some of the records. If we assume that this represents inhibition, then Bayliss and Starling's law can be demonstrated with reverse waves as well as with caudad ones, and it can no longer be assumed to be the cause of normal peristalsis.

THE DOG AS A CARRIER OF DISEASE TO MAN *

MINAS JOANNIDES, M.D.
AND
WILLIAM A. RILEY, Ph.D.
MINNEAPOLIS

Our object in this paper is to emphasize the fact that the dog acts as a carrier of disease when not properly managed. No attempt will be made to give a detailed discussion of the various diseases that a dog may carry. Our purpose will be accomplished if groups interested in public health and hygiene will consider the dog as a possible carrier and study him from that point of view.

The fact that the dog is a carrier of disease has been recognized by parasitologists and zoologists all over the world. With the exception of the work of M. C. Hall[1] in this country and Cameron[2] in England, no recent concentrated effort has been made to bring this problem before the general public or even before the medical profession. In Minnesota, some attempts have been made to bring the topic before the medical profession.[3]

There are two modes of disease transmission by the dog; first, when the dog contracts a disease and carries it to human beings, or when it acts as an intermediate host of various parasites; second, by coming in contact with some infected article and carrying the infection into the household. As a pet, the dog has become a very intimate member of the home. The average pet dog is allowed to lie on its master's bed, or even to eat from the same plate. The dog is allowed to roam, and on coming back is permitted to play with the children of the family, and thus renders possible infection with various animal parasites, skin diseases, or pathogenic bacteria.

During the last two years, we have examined the intestinal lumen of all our laboratory dogs that came to necropsy. Our observations convinced us that it would be unusual if a dog did not have intestinal parasites. Although most of the parasites have adapted themselves to the conditions found in the dog's intestine, and perhaps may not be obnoxious in the human intestine, still there are parasites, such as various trematodes, nematodes and cestodes, that are definitely pathogenic for man. The dog may carry skin parasites, such as scabies, fleas, lice or ticks. Of the diseases of man caused by the grosser animal parasites, echinococcus is the most serious. Although more than 350 cases have been reported for this country,[4] the actual number of infections is undoubtedly much greater. Practically the only primary host of the echinococcus is the dog.

[4] Joannides, Minas; and Riley, W. A.: Echinococcus Cyst in the Scapular Area, Report of a Case, Arch. Surg. 9: 537 (Nov.) 1924.

The fact that the disease is most prevalent in localities where the dog is in very intimate contact with human beings is a striking illustration of the rôle this animal plays in the transmission of human disease.

Cases of pulmonary tuberculosis in the dog have been reported. Müller and Glass[5] state that tuberculosis in the dog can be developed in one third of those inoculated experimentally. The dog apparently has greater resistance to tuberculosis than cattle. It is possible that the tubercle bacillus infecting the dog may be a distinct type. Be that as it may, the dog easily can carry human tubercle bacilli on its hair, paws or other parts of its body. Similarly, the dog may carry other infectious diseases, such as diphtheria, scarlet fever, measles and smallpox.

It is common knowledge that rabies is transmitted to man chiefly through the dog. Epidemics spring up in various parts of the world, chiefly because the dog is not controlled sufficiently to render it harmless.

It is not our intention to condemn the dog as the cause of numerous difficulties. It is the dog's master who is responsible because of his lack of education along the lines of prevention, and also because of neglect toward the animal. Our contention is that if a man likes a dog sufficiently well to make it a pet, he has a duty to perform in keeping the animal clean and training it to avoid contact with infected materials. The dog can be trained to do almost anything; therefore, it should be an easy task to teach it not to lick the baby's face or hands or take food from his plate. In the presence of infectious diseases, the dog should be quarantined with the rest of the household. Periodically, vermifuges should be given, this treatment best being carried out by the veterinarian. Similarly, the veterinarian can protect the dog's skin from infection with mange, ringworm or other skin diseases. Epidemics of rabies should be a danger signal and an indication to muzzle all dogs in the neighboring localities. Stray dogs should be disposed of. Castration may be resorted to as a means of keeping the dog at home, thus preventing, in a measure, the possibility of infection of the dog and secondarily of man. Finally, the dog should be treated as a dog and not as a human being.

Probable method by which Dipylidium infection usually occurs. From Riley and Johannsen's Handbook of Medical Entomology.

ABSTRACT OF DISCUSSION

DR. R. P. BATCHELOR, Palmerton, Pa.: We must acknowledge that the dog is a definite carrier of disease to man. Scarlet fever, diphtheria and other human diseases are known to have been spread by dogs. Human echinococcus and dipylidium infections have been traced to this source. The danger from rabies is ever present. But have we any scientific basis for believing that the common intestinal parasites of dogs are passed on to man? Puppies are notoriously full of such parasites, and their close companionship with children should cause widespread infection to them. Yet I think many of us in looking over our cases find rather interesting data. I have noticed that the children infected with intestinal parasites are in large part those with very unclean habits, and many of them give no history of close association with dogs. On the other hand, many children of families owing dogs, children who have been in constant intimate contact with these pets, have shown no evidence of any intestinal parasites on repeated stool examinations and in spite of the fact that the pets have been in many cases heavily infested. Perhaps the supposed bactericidal action of the dog's saliva may be a factor of safety in this matter.

DR. E. E. SMITH, New York: A case of a subconjunctival echinococcus cyst came to my attention in New York in the past winter in the eye service of Dr. George Ray Hare, which it was suggested might be of external origin and which may have reached the eyeball in the manner called to our attention this morning.

DR. H. F. SMYTH, Philadelphia: In the community in which I live we have had more or less rabies. There was one striking outbreak in which five or six dogs in the community were bitten and I think one person. The owner of a pet dog, a woman, came down in the morning, opened the front door, and noticed that her dog, who had been out, was acting queerly. She was afraid to let him in the house and left the dog out, and that dog ran through the town, biting a number of other dogs. The same idea of lack of responsibility is seen in the custom of people going away for a few days and leaving their pets on the town.

DR. WILLIAM J. HICKSON, Chicago: In the last week I have seen dogs imported from Ireland, a Russian wolfhound recently over, and police dogs from Germany, and I think we had better be on our guard against introducing forms of parasites they have in Europe that are not common here that might be carried by these dogs. Such investigation could be made in quarantine.

DR. OSCAR DOWLING, Shreveport, La.: I trust that we may soon have a law or regulation throughout the United States which will require that every owner of a dog shall pay $2 license for that dog, the money to be used for rabies vaccine and the employment of veterinarians to administer it. I understand that 50 cents would cover this charge; then 50 cents would be left for the town or county and 50 cents for the health department with which to carry on some other work. In Louisiana we have had occasion to send out many of these treatments. They cost us $20 each, and in some instances we have sent as many as ten or fifteen into a community where we have reason to believe $200 is more than all the dogs in that section are worth. I see no reason why we should not arrive at some arrangement by which we may protect the public.

DR. MINAS JOANNIDES, Minneapolis: There are three types of roundworms that are found in the dog and may be found also in man. These are, *Eustrongylus gigas, Trichinella spiralis* and some of the ascarids. Worms in the dog are so common that it is the unusual thing not to find them in the dog's intestine. Not all of these are necessarily pathogenic to man. I called attention to the excellent paper of Dr. Hall. Again I wish to refer to his paper because he writes extensively on this subject. As a carrier, the dog may act as an intermediate or a chief host. In some instances the intermediate host is the same for both man and dog. Such is the case of the dog flea that carries *Dipylidium caninum* both to dog and to man. With reference to the echinococcus cyst of the eye, the infection very likely was implanted through the blood or lymph stream in a manner similar to a case of echinococcus cyst of the scapular area reported by me in the *Archives of Surgery* in November, 1924. Rabies is prevalent because owners of the dog have more regard for their dog than they have for the general public. Dogs are allowed *to run loose without any restriction. In Great Britain, any* new dog that comes into the country is quarantined for six months before it is let loose. A regulation of this sort might be of some help in this country. I should like to emphasize again the importance of quarantining pet animals during the presence of a quarantined disease in the household. Under the present régime we keep children from school, but we allow the infected dog to play with children of the neighborhood and thus carry disease from that household. The point of emphasis in this paper is the necessity for the education of the medical profession and the public along these lines, rather than placing restrictions on the dog and its master by means of legislation. If we educate the public by having talks in churches, luncheon clubs and schools, and illustrate our points by means of lantern slides or specimens, I think the public will be favorably impressed. The method instituted by Dr. O'Brien at the University of Minnesota for exhibiting preventive medicine measures in a recent health exhibit is a very practical one.

STONES IN THE KIDNEY PELVIS

A NONOPERATIVE METHOD OF REMOVAL WITH THE AID OF THE CYSTOSCOPE

BRANSFORD LEWIS, M.D.
ST. LOUIS

To meet the requirements demanded by a person of the stone-forming habit may be very difficult. The patient concerned in this report was subjected to so many operations for the removal of stones from both kidney pelves and ureters that further operative measures became a serious question. In view of his lowered vitality and the distressing after-effects of operations, *something else had to be done.*

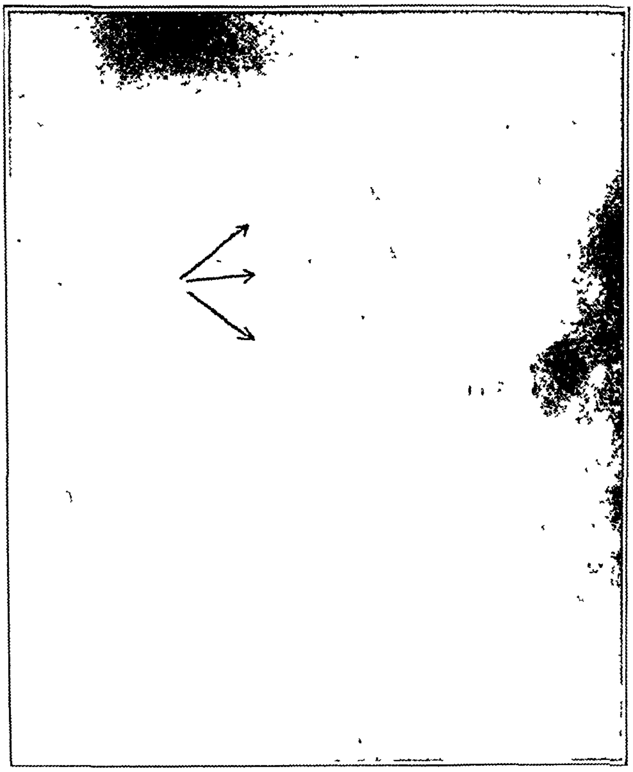

Fig 1 —Stones in left kidney pelvis and catheter in left ureter, Dec. 21, 1923.

REPORT OF CASE

F. K., a student, aged 22, who first consulted me in June, 1920, for a year had been having typical attacks of renal and ureteral colic on the left side, accompanied by the passage of bloody urine and occasionally a small stone. July 10, by cystoscopy a stone was removed from the left ureteral orifice, after slitting with ureteral scissors.

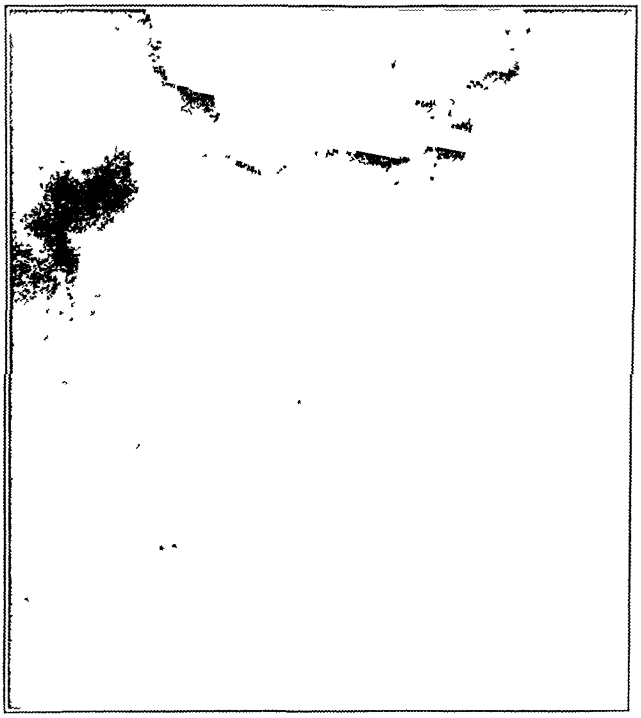

Fig 2 —Dilated left kidney pelvis and ureter, March 6, *1923:* stones gather in lower calix

The patient was placed on a meat-free diet, with forced fluids, and was apparently free from further trouble for nearly a year. But, in the summer and fall of 1921, the urine clouded again, and examination disclosed a stone the size of a hazelnut in the right kidney pelvis. No shadow or evidence of stone was found in the left kidney at this time

November 9, under general (ether) anesthesia, a stone was removed with some difficulty from the right pelvis. It was so adherent that it was partly broken in the removal, but all the pieces were picked or washed out. On recovery the urine was again clear, and the wound was healed in a month There was some excess of phosphates at this time. About March 23, 1922, the patient passed two small stones. April 15, cystoscopy and the roentgen ray showed some shadows of small stones in the left kidney pelvis, four of which passed after pelvic lavages and ureteral dilatings. Acid sodium phosphate and a preparation of hexamethylenamin were given internally.

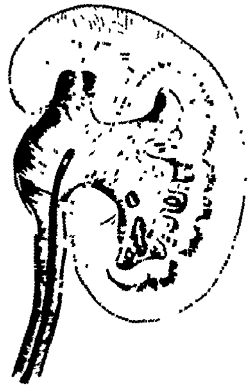

Fig. 3 —Natural position; stones in lowermost pocket

March 5, 1923, stone shadows were again demonstrated in the left kidney pelvis, low down One stone passed into the ureter in the next few weeks and was hung up there until removed by left ureterolithotomy on April 26. This stone was the size of a hazelnut. Irrigation through a retained ureteral catheter, slow convalescence and return home after many months of illness followed. November 15, cystoscopy and the roentgen ray showed one larger shadow in the right and two *smaller* ones in the left kidney.

November 28, right nephrolithotomy was performed. The patient was very anemic (red cells only 2,800,000) during this period, and was given a blood transfusion December 8, with benefit. But it was apparent that he could not stand more major operating, notwithstanding the presence of more shadows in the left kidney pelvis, the right being kept free and clear by frequent pelvic lavages.

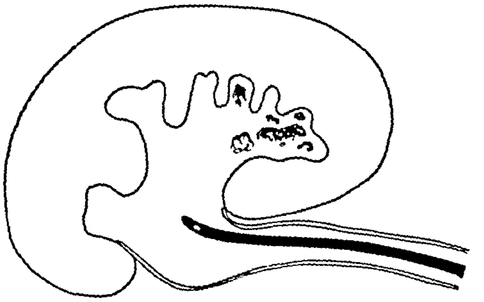

Fig. 4.—Changing the position, elevating the dependent pocket and lowering the outlet.

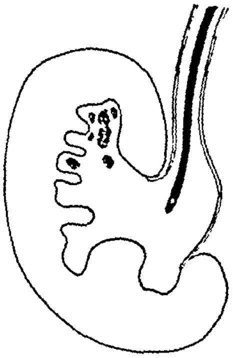

Fig. 5.—Further change in position, increasing the effect shown in Figure 4.

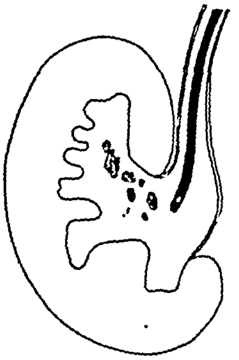

Fig 6.—Pelvis and upper ureter filled with injected fluid providing for release and escape of stones

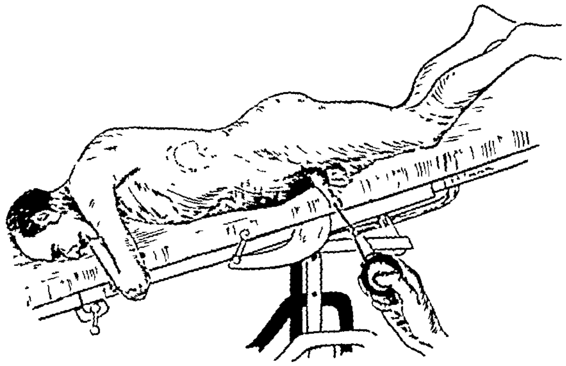

Fig. 7.—Injecting the pelvis while in the inverted position.

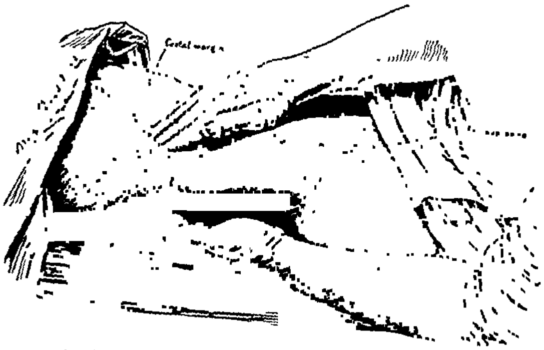

Fig. 8.—Applying succussion to the flank while in the position shown in Figure 7. (After Kelly and Burnham)

It was at this time (Dec. 19, 1923) that I first put into effect the measure to be submitted. As may be seen by the roentgenogram (Fig. 2), the left pelvis and ureter were both well dilated, indicating that if a stone, even of considerable dimensions, were dumped into the pelvic end of the ureter, it would stand a good chance of passing through the ureter, the caliber of which had been enlarged by the use of bougies and dilators. Roentgenograms of this period (Fig. 1) showed several small shadows and one or two large ones in the lower calix which formed a pocket at the bottom of the left pelvis,

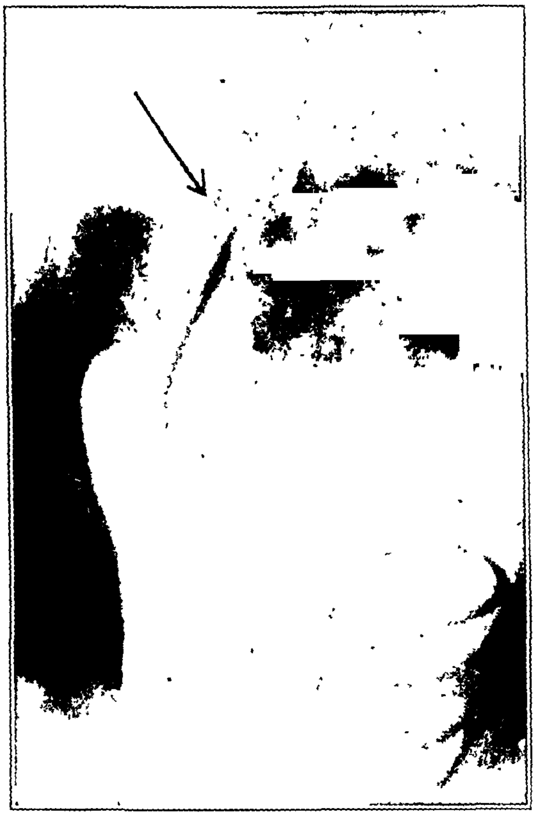

Fig. 9.—Good sized stone in left ureter at end of catheter, April 18, 1923.

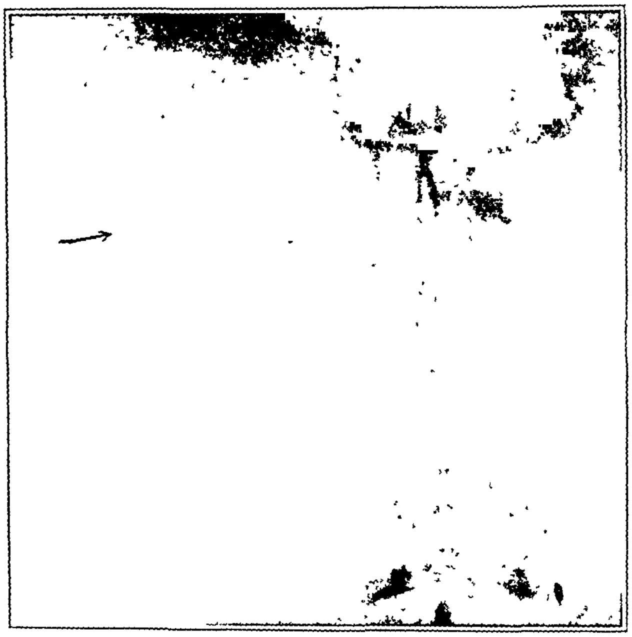

Fig. 10.—Two stones in lower calix of left kidney pelvis; March 18, 1924, removed by cystoscopy and shaking

the most dependent location. Obviously, they were liable to remain indefinitely unless removed by active measures of some sort. It occurred to me that if the kidney could be turned upside down, so to speak, and the pelvis distended with fluid at the same time, both the release of the stones and their escape from the cavity might be promoted. This object might still further be enhanced by succussion movements and energetic massage applied to the affected kidney through the lumbar wall. The successive stages of these manipulations are shown diagrammatically in Figures 3 to 8. They were carried out for the first time on the morning of Dec. 19, 1923; and when the patient was dismissed he was told in jest that he would pass a stone at 3 o'clock that afternoon. On calling the next morning, I found the patient wreathed in smiles and much pleased in that at just 3 o'clock the previous day he had passed a good-sized stone, shown in the accompanying collection.

The succussion treatments were administered at intervals during the following year, with results so gratifying that about seventy-five stones have been evacuated; and during the last five or six months, both kidneys have been kept fairly clear of concretions.

A list of the treatments with their results is given in the accompanying tabulation.

The patient meantime has improved much in his physical and mental condition and has increased in weight; the urine has been much clearer than formerly, synchronizing with the roentgen-ray evidence, which for several months has failed to show stone shadows on either side. But, notwithstanding this fact, small concretions have been brought down on numerous occasions by the treatments, although they were not shown by the roentgen ray. They have been too small to be shown by the ray. While that does not speak altogether well for the accuracy of the ray, it does support the efficiency of the treatments, since all such concretions, if left in, would grow and in time become demonstrable by the ray and also produce their destructive effects on the kidney. As it is, the patient is in better general and local condition now than he has been during my previous acquaintance with him (five years).

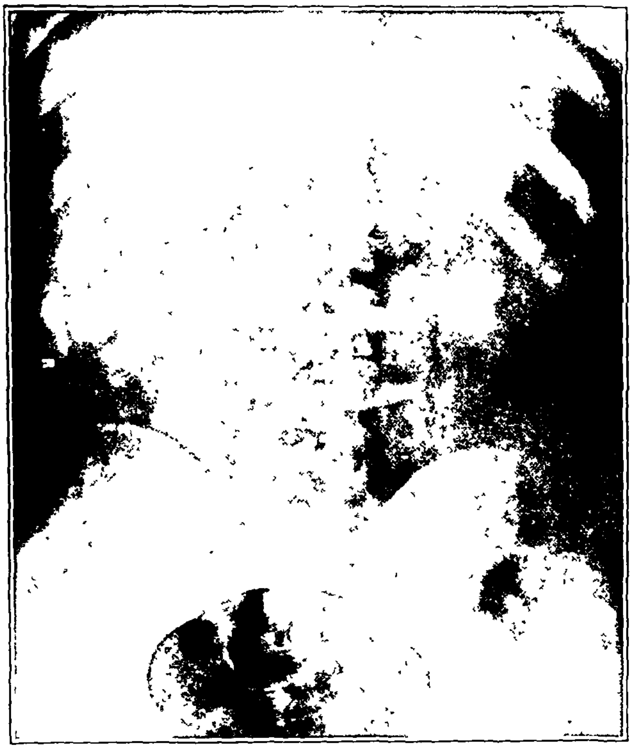

Fig. 11.—No stone shadows, after succussion treatments

COMMENT

It will be noted that a considerable number of the stones thus removed are of very good size.

It is realized that other questions might be brought up, as to the propriety of elevating or replacing the kidney to favor drainage—methods of doing away with the stone-forming habit, etc.—but these questions will not be taken up in this presentation. I merely wish to describe a nonoperative method of removal of stones from the kidney pelvis that has given gratifying success and relieved a tense situation.

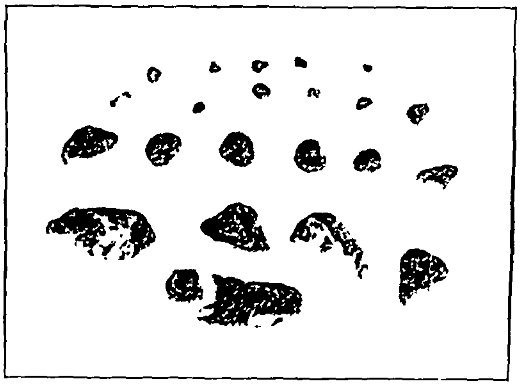

Fig. 12.—Stones from the kidney pelvis, removed during the year 1924 by cystoscopic succussion methods.

FINDINGS, TREATMENTS AND RESULTS

Cystoscopy and Succession	Results
1. Dec. 19, 1923, 8 a m.	Dec. 19, stone passed 3 p. m.
2. Dec. 24, 1923, 8 a. m.	Dec. 26, one stone passed
3. Dec. 28, 1923, 8 a m.	Jan. 2, 1924, two stones passed
4. Jan. 8, 1924	Jan. 10, large stone passed
5. Jan. 16, 1924	No stone passed
6 Jan. 23, 1924	No stone
7. Jan. 27, 1924	No stone
8. Feb. 1, 1924	No stone; irrigation fluid returns clearer
9. Feb. 6, 1924	Feb. 9, one small stone after two days' colic
10. Feb. 11, 1924	Feb. 14, two small stones
11. Feb. 14, 1924	Feb. 16, one small stone
12. Feb. 20, 1924	None
13. Feb. 23, 1924	None
14. Feb. 26, 1924	None
15. March 1, 1924	March 2, one stone
16. March 10, 1924	None
March 18, 1924	Roentgen ray showed three stones in left pelvis
17. March 21, 1924	March 21, one stone
18. March 25, 1924	None
19. March 27, 1924	March 28, two stones
20. April 1, 1924	None
21. April 6, 1924	None; goes home
22. May 6, 1924	May 6, one stone
23. May 11, 1924	May 13, one stone
24. May 16, 1924	None
25. May 21, 1924	May 21, colic same day; required four days for passage of largest calculus, May 25
26. June 3, 1924	None
27. June 19, 1924	None
28. July 2, 1924	July 2, two stones
29. July 18, 1924	Roentgen ray showed two small shadows lower pole left kidney pelvis; large shadow absent
30. Aug. 1, 1924	None
31. Aug. 18, 1924	Aug. 23, one stone after two days' colic
32. Aug. 26, 1924	Catheter and roentgen ray; one shadow, left pelvis
33. Aug. 30, 1924	Succussion treatment; no stone
34. Sept. 10, 1924	None
35. Nov 10, 1924	None
36. Nov. 15, 1924	Nov. 16, one stone
37. Dec. 15, 1924	Dec. 17, one stone
38. Jan. 20, 1925	Colic three days; large stone passed, Jan. 24
Jan. 25, 1925	Tonsillectomy
39. Feb. 3, 1925	None
40. March 10, 1925	Roentgen ray showed no shadows; urine drained clear
41. March 20, 1925	Roentgen ray failed to show shadow; March 23, small stone passed
42. April 2, 1925	April 4, colic; April 5, fair sized stone passed
43. April 7, 1925	April 7, shower of small stones (about ten) passed within two hours after succussion treatment

The transit of a stone is described by the patient as follows: After feeling bad, with headache, nausea, nervousness and sleeplessness for three days, cystoscopy was done and succussion treatment given, March 20, 1925, at about 8 a. m. While considerable relief from the symptoms appeared on the same day, it was not until the following morning at about 8 o'clock that the patient felt the stone moving down the ureter. This he said he distinguished with certainty, the stone passing through the entire ureter in the space of about thirty minutes. On the stone escaping from the ureter into the bladder, the patient felt instant and complete relief. The stone passed from the bladder at the second urination after its entrance into that organ.

Clinical Notes, Suggestions and New Instruments

A SIMPLE SPLINT FOR BASEBALL FINGER

PHILIP LEWIN, M.D., CHICAGO

This is a simple splint which I have found very effective. It is useful in the treatment of baseball finger, mallet finger[1] or "drop phalangette,"[2] and arthritic flexion of the end phalanx. The principle may be useful in the treatment of hammer toe.

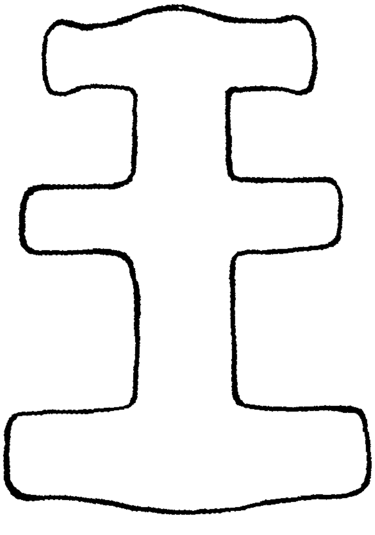

Fig. 1.—Pattern for splint.

It is made of aluminum, although duralumin, copper, brass, German silver or silver may be used. It is very light, self-retaining and easily adjustable to any position, including hyperextension. It is permeable to the roentgen ray, can be immersed in water, and is inexpensive. The splint can be made to fit so snugly that it must be "soaped" or wet to be removed, like a tight band ring. It can be worn under a glove, and one of my patients drives her car while wearing it.

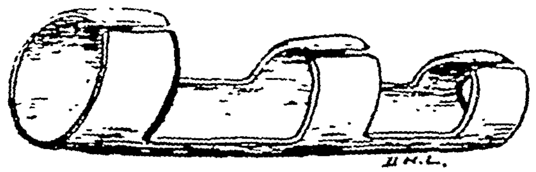

Fig. 2.—Splint.

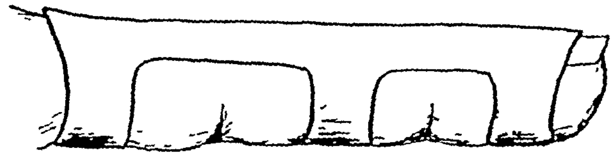

Fig. 3.—Splint applied.

A pattern is made as shown in Figure 1. The pattern is then shaped to that of Figure 2 and applied as in Figure 3. During the latter part of the treatment, each patient should have two splints; one unlined to be worn if the hand is to get wet; the other lined with chamois for the dry hand.

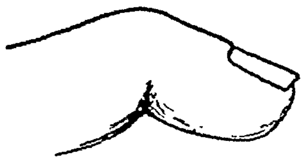

Fig. 4.—Flexion deformity of distal phalanx; "drop phalangette."

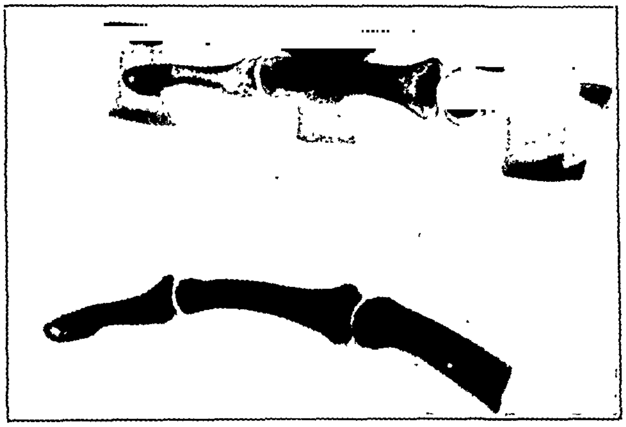

Fig. 5.—Finger with and without splint.

RECURRENT CARCINOMA OF BREAST, WITH ROENTGEN-RAY FIBROSIS *

HAROLD SWANBERG, M.D., QUINCY, ILL.

Mrs. B., aged 48, referred to me, June 8, 1920, by the Mayo Clinic, for postoperative roentgen-ray therapy for carcinoma of the breast, had not had any serious previous illness, except diphtheria when a child. Her general health had always been good. She had no children. In October, 1918, she noted a small lump in the right breast, which was about the size of a quarter and was not associated with any pain. She immediately consulted a physician, and two days later had the whole breast removed, but did not have any of the axillary glands dissected, for a radical operation was not thought necessary and was not contemplated unless a pathologic examination revealed malignancy. Sections made from the growth removed were reported nonmalignant. In March, 1920, she noticed a small nodule in the skin of the right axilla. This was removed and found to be malignant. She then went to the Mayo Clinic, where a radical breast amputation was done, April 12. What the Mayo Clinic thought of the case can be judged by the following extracts from a letter received May 3, 1920:

"Mrs. B. came to us, April 7, with a recurring carcinoma of the right axilla following amputation of the breast elsewhere in October, 1918. She was operated on here, April 12, at which time Drs. C. H. Mayo and Pemberton excised the scar of the old breast amputation, including all of the pectoralis minor and all except the clavicular attachment of the pectoralis major, and dissected out the nodes in the right axilla, which were extensively involved. The junction of the sternum and the first rib on the right side was nodular and slightly enlarged; the tissue around this point was adherent but was hard and bonelike, and no specimen could be removed. It is possible that this is bony metastatic malignancy.

1. Wilson and Cochrane: Fractures and Dislocations, 1925, p. 319.
2. Stern: Am. J. Orthop. Surg. **6**: 484 and 518, 1908-1909.

* Read before the Central Illinois Radiological Society, Quincy, Ill., May 19, 1925.

"She received one roentgen-ray treatment here, April 26, and as she expects to visit in this vicinity for some time she will probably receive her second treatment here also. On her return home we have advised her to consult you for further treatments, although the ultimate prognosis is most unfavorable."

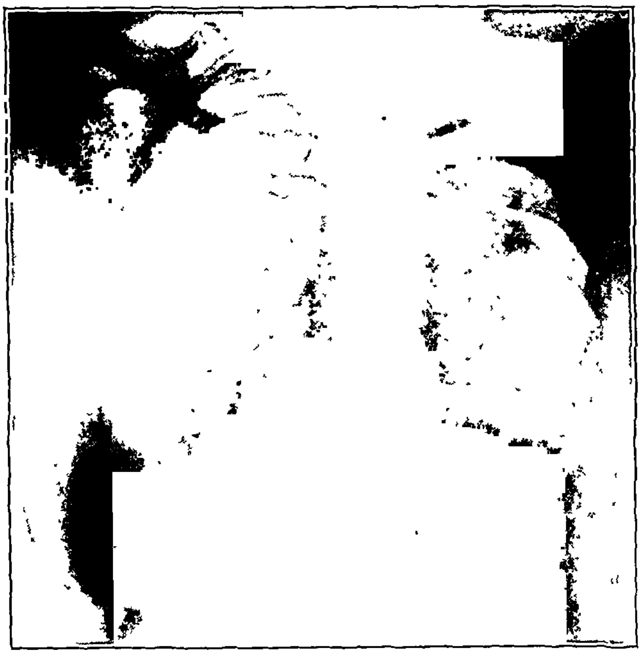

Fig. 1.—Condition of chest, Sept. 22, 1922.

After having several series of roentgen-ray treatments at the Mayo Clinic, the patient reported to me, June 8, 1920, for postoperative roentgen-ray therapy. A course of treatment was administered and repeated in July, September, December and the following March and June. The treatment consisted of the usual one that roentgenologists were administering at that time. It consisted of exposures of multiple small skin areas, a 9½ inch gap, 5 milliampere current and 7 inch skin distance being used, with 4 mm. of aluminum and a piece of sole leather as filters. The time factor averaged about eight minutes. Later the filter was increased to 5 mm. of aluminum and the distance to 8 inches. While no roentgenographic examination of the chest was made at first, several fluoroscopic examinations were made, and all were negative. As the result of the roentgen-ray treatment, the patient experienced some very severe skin reactions. In fact, they were so marked as to give me considerable concern, for I felt that the patient was unduly susceptible to the rays. On one occasion a distinct skin reaction appeared on the posterior section of the chest a day after several treatments had been administered on the anterior surface. Jan. 4, 1922, I felt that enough radiation had been administered, but further correspondence with the Mayo Clinic advised me to continue to give a series of treatments every three or four months; therefore, an additional series of treatments was administered in January and May, 1922. These series consisted of two large areas of exposure, anteriorly and posteriorly over the right chest and axilla, with a 10½ inch gap, 5 milliamperes, 12 inch skin distance, and 6.5 mm. aluminum and a piece of sole leather as filters, with fifteen minutes time for each area. About April, 1922, the patient developed a cough, which was dry. She had no dyspnea or pain. The cough lasted all summer and did not disappear until about September. During this period, however, she was feeling fine and was steadily gaining in weight. September 22, the first roentgenograms were made, followed by an additional examination, December 29, and a third examination in May, 1925. The date of the last roentgen-ray treatment was May 23, 1922.

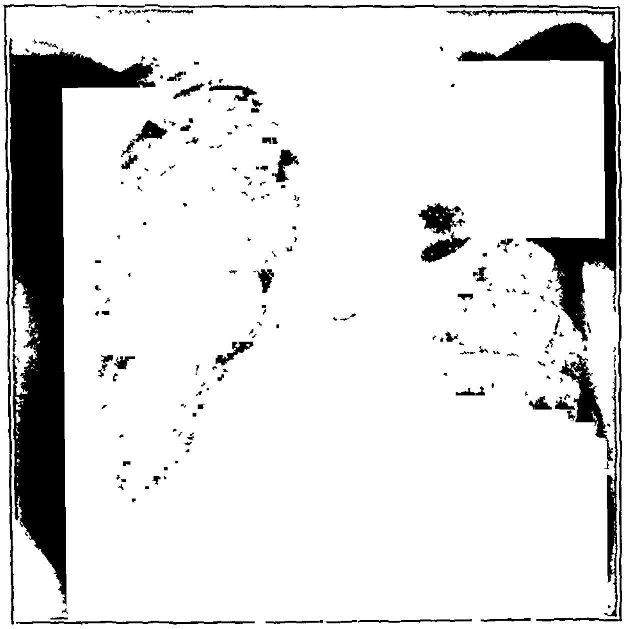

Fig. 2.—Condition of chest, Dec. 29, 1922.

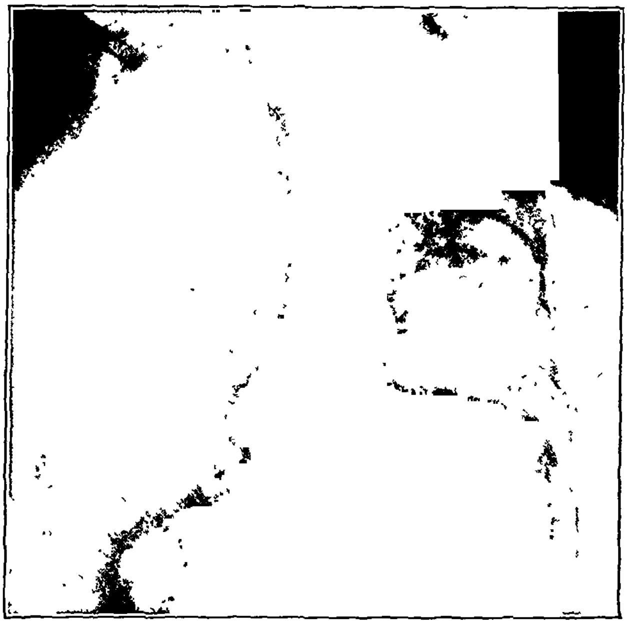

Fig. 3.—Condition of chest, May 16, 1925.

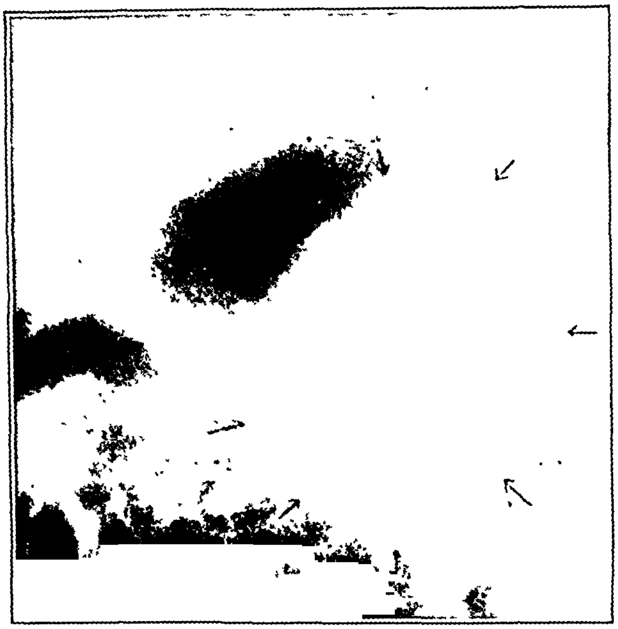
The roentgenograms clearly show a marked fibrosis present in the right chest. In fact, practically no lung tissue is apparent in the upper half of the right chest at the last examination. The diaphragm is elevated on this side; the ribs are more oblique, and a distinct scoliosis is present. The left lung presents a distinct compensatory emphysema, the only portion of the right lung that is aerated being a small part at the base. The films also demonstrate that the condition is not clearing up; in fact, the density was more marked at the last examination. Clinically, however, the patient enjoys excellent health and the lung fibrosis apparently gives her no concern. The cough has disappeared, and there is no dyspnea or pain. A very marked telangiectasis is present nearly all over the chest, but there is no clinical evidence of any recurrence of the original growth. Needless to say, the patient is extremely grateful in view of the grave prognosis originally made.

731 Hampshire Street.

TUMOR OF THE BODY OF THE PANCREAS*

Jacob Buckstein, M.D., New York
Consultant in Gastro-Enterology, U. S. Veterans' Bureau; Assistant Roentgenologist, Bellevue Hospital (in Charge of Gastro-Intestinal Roentgenology); Assistant Attending Physician, New York Polyclinic Medical School and Hospital

The accurate clinical diagnosis of tumor of the body of the pancreas is sufficiently difficult to warrant the report of clear evidence on which such a diagnosis may be based. This evidence is roentgenographic. As noted in the accompanying roentgenogram, the stomach, in addition to being displaced upward, shows a smooth crescentic defect involving the greater curvature. There is also downward displacement of the small intestine. On this indirect evidence, a diagnosis of tumor of the body of the pancreas was made. This was verified on surgical exploration by Dr. Arthur M. Wright, visiting surgeon to Bellevue Hospital. The tumor was a large pancreatic cyst.



Tumor of the body of the pancreas, indicated by arrows.

PRIMARY TULAREMIA OF THE EYE

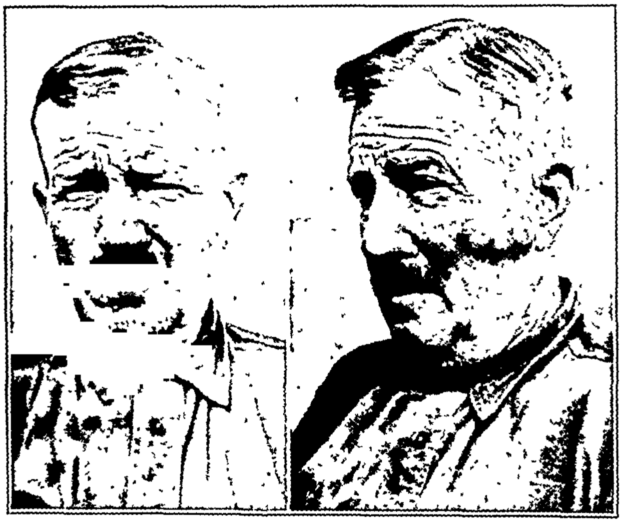
Malcolm C. Pfunder, M.D., Miles City, Mont.

The paucity of reported cases of tularemia with the primary infection in the eye makes it seem desirable to add one more to the four that have been reported by Vail, Sattler and Lamb of Cincinnati, and Martin[1] of Phoenix, Ariz.

REPORT OF CASE

W. C. F., aged 63, a farmer, who consulted me, April 11, 1925, noticed several wood ticks on the horses while harnessing his team, April 6. He removed these with his fingers, and while so doing a foreign body was blown into his left eye; he removed this with his finger. April 8, what he described as a "pimple" appeared on the conjunctiva of the lower lid of the left eye, and a marked swelling appeared just in front of the left ear. April 11, when he appeared for treatment, there was tremendous swelling extending from the superciliary region to the upper lip, and backward to the ear, the lids being so swollen that the patient was unable to open the eye. The bulbar conjunctiva was so swollen that it hung downward from above and extended upward from below so that the cornea was seen only through a slit 3 mm. wide. On the palpebral conjunctiva of the lower lid there were two small ulcers about 2 mm. in diameter. Smears made from the conjunctiva showed many pus cells but no organisms. The temperature was 101 F. when first observed; no white blood cell count was done. April 14, the chemosis became so marked that the cornea became "steamy" in appearance. The patient was then hospitalized, and continuous hot applications were used on the eye. Under this treatment the swelling about the eye diminished considerably, and the cornea became more normal in appearance, but the bulbar conjunctiva remained markedly swollen. As the edema of the left side of the face disappeared a ridge, extremely hard and about 2 cm. high became visible, extending from the outer canthus to the preauricular lymph gland. This gland meanwhile had continued to enlarge until it was as large as a hen's egg and very hard. The eye continued to improve, and, April 24, the patient went home against my advice. The right eye remained entirely normal.

April 25, the article by Francis[2] appeared; and, seeing a similarity between this case and those reported from Cincinnati, I drove to the patient's home, 60 miles away, to observe his surroundings and to obtain a specimen of blood from an agglutination test. From the window of the house a view could be obtained of a long, gentle slope on which many small, white spots could be seen. These proved to be the bodies of rabbits of the so-called "Jack" variety, all dead from natural causes. It is interesting to observe in this connection that people who have lived a long time in Montana, those who like to be called "old timers," all tell about a periodic epizootic among the rabbits, which appears about once in seven years and kills them by the thousand. In the light of modern knowledge, it seems quite probable that this epizootic is tularemia. A search was made in the sagebrush for the common Montana wood tick, *Dermacentor andersoni* Stiles, but unfortunately the day was cold and none were found, though the patient informed me that many could be found on warm days. A specimen of the patient's blood was drawn into a Keidel tube, and after returning to the office, I mailed the serum separated and diluted with an equal amount of neutral glycerin, to the Hygienic Laboratory of the U. S. Public Health Service, Washington, D. C. May 2, a wired report stated, that the serum was positive for tularemia in a dilution of 320.



Appearance of patient with primary tularemia of left eye with secondary involvement of preauricular lymph gland, forty days after onset of illness.

May 18, I again visited the patient. The eye was considerably improved, though there was still considerable chemosis. The preauricular lymph gland was even larger than before and had begun to soften in three areas, giving a distinct sense of fluctuation. Photographs showing the enlarged gland and the thickening along the course of the lymphatics, from the eye to the preauricular gland, were taken on the occasion of this visit, forty days after the onset of the disease. At this time the patient's temperature was 99.6 F.

LIVER FUNCTION TESTS

The proposal to employ the quantitative measurement of urobilin, or its precursor urobilinogen, in the urine as an aid to diagnosis is not a new one. Urobilinogen is almost invariably present in the urine of man. Urobilin rarely, if ever, appears in the freshly voided urine; but it can readily be formed from its antecedent, so that the two closely related substances may be regarded as having a common history and significance. Fortunately, there are fairly satisfactory methods for the quantitative estimation of these pigmentary compounds. Their application has shown that large variations occur in the output of urobilinogen in the urine; and it has been the study of these that has raised the question of their possible diagnostic significance. The literature of the subject reveals an alternation of enthusiasm and doubt. Not a little of the uncertainty is attributable to the conflict of opinion regarding the genesis of the urobilinogen.[1] Most writers have followed the leadership of Friedrich Müller in attributing to urobilinogen an enterogenous origin. According to this conception, bilirubin, entering the intestine, undergoes gradual changes and eventually becomes transformed, through bacterial changes in the intestine, into urobilinogen. Micro-organisms are thus made to play a part in the genesis of the compound. The belief that urobilinogen may be formed in the kidney, through reductive processes occurring in that organ, appears to have been definitely disproved. The same could not be said regarding other nonenterogenous theories until recently.[1] If further evidence were needed in substantiation of the intestinal origin of urobilinogen, it could be found in the observations of Wallace and Diamond[2] of New York. They show, through experiments on animals, that in exclusion of bile from the intestinal canal by ligation and excision of the common duct, urobilinogen does not appear in the urine, even though the liver may be severely damaged. When, however, the flow of bile is reestablished by anastomosis between the gallbladder and the duodenum, or when bile is administered by mouth, urobilinogen again makes its appearance. The finding of small quantities of the substance in the intestinal canal after occlusion of the common duct is easily explained by the demonstrated excretion of bilirubin from the general circulation directly through the intestine, where the bile pigment becomes converted into urobilinogen through the subsequent bacterial transformations.

Until the opponents of the enterogenous theory can marshal more convincing evidence, it may be accepted as a working hypothesis. Experimentally, it has been found by Wallace and Diamond that in parenchymatous changes of the liver there occurs a marked increase in the urinary output of urobilinogen. If this means, as we may properly suppose, that the reabsorbed urobilinogen is not properly mobilized by the damaged liver and hence is eliminated from the blood by the kidneys in greater than usual amounts, the increased output truly is an indication of hepatic disorder. In harmony with this, it has been observed that the pathologic conditions in which urobilinogen is eliminated in excessive amounts can be classified in two main groups. One of these comprises diseases of the liver and biliary tracts—conditions showing acute and subacute hepatic changes or exacerbations associated with chronic processes. In the course of the slowly progressive chronic liver lesion, the output of large amounts of urobilinogen is said not to be constant. This is probably attributable to the ability of the organ to perform its normal metabolic function by compensatory growth of new liver tissue. The other group of diseases characterized by large urobilinogen output comprises hemolytic disturbances in which the outcome is due to the increase in the formation of bile pigment and a consequent relative insufficiency of the liver.

Facts such as the foregoing represent the possible basis for the choice of the "urobilinogen test" in the interpretation of liver disorders. The inevitable limitations of such aids to diagnosis should be frankly recognized. As Wallace and Diamond point out, any functional test designed to measure liver abnormality must be limited in its application and interpreted with great caution in terms of liver function. In any disease of the liver, they add, it is unlikely that all functions are deranged or at least equally involved; and, furthermore, there is no known single test that measures hepatic function as a whole. Bearing these shortcomings in mind, the New York clinicians advocate the use of the urobilinogen test as a routine laboratory measure in all urine examinations. We are assured that in icterus or in latent icterus, in hepatic disorders, in the anemias, in malaria, in infections, in malignancies and in intoxications it will supply an important adjuvant in the routine diagnosis, and will often aid in the interpretation of intricate and obscure clinical conditions.

---

[1] The Origin of Urobilin, editorial, J. A. M. A. 85:518 (Aug. 15) 1925.

[2] Wallace, G. B., and Diamond, J. S.: The Significance of Urobilinogen in the Urine as a Test for Liver Function, with a Description of a Simple Quantitative Method for Its Estimation, Arch. Int. Med. 35:698 (June) 1925.

Thus, the constant presence of urobilinogen in catarrhal jaundice, and its total absence in mechanical icterus, such as is encountered in carcinoma of the head of the pancreas and of the biliary tract, forms a marked distinguishing diagnostic feature between the benign forms of jaundice and those due to malignant causes. The urobilinogen test does not always coincide in its character with the recently much vaunted test with phenoltetrachlorphthalein. Wallace and Diamond remind us, in this connection, that retention of the dye does not necessarily indicate a deficiency in the performance of the normal metabolic function of the liver, but merely points to a lessened capacity of this organ to eliminate foreign substances. The newer technic for the urobilinogen test brings it within the scope of any clinical laboratory.

CHEMICAL WARFARE

"The pacifists," said General Fries[1] in a recent address, "are the fundamentalists of international relations. They won't believe half what they see, nor anything they hear that is based on history." Beginning with Cain's destruction of Abel by the use of a club, warfare has progressed through the Greek phalanx, the Roman legion, the spear, the bow and arrow, the battle ax, the sword and armor of steel to cavalry, to gunpowder and explosives, to "tanks," aeroplanes and the so-called war gases. Each of these innovations was met with cries of horror by ardent pacifists who felt that man's inhumanity to man was becoming quite too inhumane.

As indicated by General Fries, nations never hesitate in times of war to use any weapons for offense or any methods of defense that science or ingenuity can provide. The United States, on the advice of John Hay and Admiral Mahan, refused to sign the Hague agreement on war gases. Hay realized that violation by a single nation rendered such an agreement nugatory. And when Germany began the use of gas in the World War, all other nations quickly followed.

Those most familiar with the actions and properties of war gases contend that their use is more humane than that of explosives. While gas produced many casualties in the war, records of the Surgeon General's Office indicate fatalities only about one twelfth of those resulting from wound-producing agencies.[2] The argument is made that once the use of such methods is conceded, science will go on to more and more terrific weapons. To this the chemists answer, as does Haldane[3] in his notable essay, "Chemistry and Peace," that we have apparently reached our limit because more powerful explosives would be as dangerous to the users as to those against whom they might be employed. And it must be remembered that when more efficacious methods are discovered, sooner or later some nation, fighting a war which it has convinced itself is a righteous war, will use that method. Has there ever been recorded a conflict in which each contending nation did not feel that it fought on the side of truth and morality and righteousness?

Haldane is convinced also that it is unlikely that more poisonous gases will be found than those we now have, and that the respirators used in gas defense are adequate in protection. Far more probable, he believes, is the development of skin irritants more unpleasant than mustard gas. The whole argument of the great British chemist is not for war or for chemical methods of warfare, but for increasing study and knowledge of chemical methods and for the best application of that knowledge for the good of man. With this argument for preparedness and research, none can wisely disagree.

ANHYDREMIC ACIDOSIS

The treacherous features of that somewhat insidious entity known as anhydremia have begun to receive more serious consideration as the frequent occurrence of the condition is becoming recognized.[1] In poisoning with war gases, the concentration of the blood develops as a significant symptom. Influenza and the attendant pneumonias have furnished illustrations of its consequences. A critical point in the management of extensive superficial burns arises when the circulating fluid concentrates. Probably the most frequent occurrence of anhydremia is in infancy when diarrhea and vomiting contribute to the retrenchment of the circulation in fluid. The manifestations themselves have been fairly well recognized; the relief brought by the therapy of fluid replacement is readily understood; but the more intricate features of the dehydration that engender severe symptoms are all too little understood.

Fundamental among them doubtless is the necessarily impaired circulation that must, in not a few instances, lead to impoverishment of the tissues in oxygen, just as severe hemorrhage may. One consequence Clausen[2] has clearly demonstrated to be an acidosis due in large measure to lactic acid. The latter is regularly formed in the course of muscular contraction, being removed during the period of rest by local oxidation, by resynthesis to some more complex tissue component, such as glycogen, or by transport to other metabolizing organs. The quantity in actual circulation is minimal, and little is eliminated in the excreta. As Clausen points out, under normal conditions of activity, circulation and oxygenation, the removal of lactic acid from

[2] Clausen, S. W.: Anhydremic Acidosis Due to Lactic Acid, Am. J. Dis. Child. **29**: 761 (June) 1925.

the seats of its origin is so rapid that the alkali reserve of the body as a whole remains practically unaffected. Whenever the circulation or the processes of oxidation become insufficient, the rate of removal of lactic acid will be less than its rate of production, so that the concentration in the blood will rise, and the alkali reserve of the tissues (including the blood plasma) will fall. As soon as the rate of production of lactic acid exceeds the rate of its removal by even the normal mechanism, lactic acid acidosis may result.

This happens, as Clausen demonstrated, in children in cases of cardiac decomposition for obvious reasons. With improvement of the circulation, the lactic acid promptly disappears from the blood. It has now been observed in the anhydremia so characteristic of "alimentary intoxication," lactic acid joining with retained acid phosphate and perhaps other organic acids to provoke the lowering of the alkali reserve—the true acidosis. It is a significant fact that ketosis (in which beta-hydroxybutyric and aceto-acetic acids arise) is not conspicuous in cases of lactic acid acidosis. The acidosis due to the ketone substances is best relieved by glucose and insulin, which overcome the carbohydrate starvation that induces it. Lactic acid acidosis is adequately relieved by treatment of the underlying circulatory condition. Fluid to overcome the anhydremia is the foremost requisite. Alkalis may be a menace, leading to edema or tetany through alkalosis. Intravenous or intraperitoneal infusions of replacement fluid may be life-saving.

THE AMERICAN PHYSICIAN IN FACT AND IN FICTION

Criticism of the medical profession is, in some places, a favorite "indoor sport." On the one hand, the physician may be charged with remaining aloof from public affairs and his share of responsibility for the civic welfare of his fellow men; in another quarter, he may be assailed for undue intervention and for interference with the much vaunted "personal liberties" of his compatriots.

The critics are wont to forget that the art of medicine and the practitioner of any generation represent the outcome of evolutionary changes. From the earliest times, medicine has been a peculiar blend of superstition, empiricism and "that kind of sagacious observation which is the stuff out of which ultimately science is made." In the New World there came a demand for physicians long before there existed facilities for their proper training or means for their proper support. Only in comparatively recent times have the hospital and the university become adequately available in America for training in medicine. Changes in our educational system have naturally not progressed far in advance of the social system and novel economic conditions that this country has presented.

Perhaps a better realization of the unusual environment in which medicine was forced to develop in America from colonial times until quite recently would soften the asperities of the present day critic. The history of medicine in America with its apprenticeship system and the lack of the continental type of education may at any rate serve to explain, if it does not excuse, some of the "crudities" of the earlier days. In discussing the effects of the rapid expansion of population over an enormous territory, Flexner[1] has presented a vivid picture of the consequences on the medical profession. The inevitable happened. Loose and shifting bands of practicing physicians, calling themselves a faculty, tried to impart, chiefly by lectures, to heterogeneous, uneducated groups of students the empiric knowledge—sound and unsound—which they themselves possessed. First and last, Flexner states, American towns have produced more than 400 such medical schools. The teaching of medicine on these terms was directly, in cash, and indirectly, in prestige, a profitable business. In time the medical profession—to its credit be it said—undertook itself to set its own house in order, and with such marked success that schools of this extreme type have within the last decade practically disappeared.

The critic and the reformer are by no means ready, however, to let bygones be bygones. Thus, Flexner remarks: "The medical profession now knows better; but large sections of the people have not yet unlearned the bad lesson they were then taught; so that medical sectarians employing a technic compounded of illusive promises, bragging and advertising operate profitably on a scale that would have amazed, perhaps even shocked, the regular profession in the heyday of proprietary medical education." Amid such circumstances it is refreshing to read a worth-while tribute to the country doctor, such as the late Vice President Thomas R. Marshall has published in his "Recollections"[2] regarding his father.

> I think, if service is to be the true mark of greatness in a people, all these other wonders of a wondrous age and state must pale into insignificance beside the service and sacrifice of the country doctor. Who now remembers the conditions under which he sought to minister to minds and bodies diseased? Who now, by any stretch of the imagination, can bring to view the awful roads, the inhospitable houses that were called homes, the lack of furnaces, bathrooms, hot water, electricity, gas; mud everywhere; cracks in the houses everywhere; children waking in the morning with their blankets covered with snow; huge fireplaces where you roasted on one side and froze on the other? And add to it all a malarial climate. Chills and fever—fever and chills. Day in and day out, night in and night out, storm and sunshine, the country doctor went his rounds.

Here is a heartfelt appreciation of a real American physician. Who shall deny that he was the prototype of many of the pioneers of our profession in the New World?

Current Comment

SINGLE INJECTION METHOD OF VACCINATING DOGS AGAINST RABIES

Japanese investigators, in 1921, found it possible to immunize dogs against rabies by a single subcutaneous injection of glycerinated fixed virus that had been attenuated by the addition of phenol (carbolic acid), and their work was confirmed[1] in this country. It appears now, from more recent investigation,[2] that the single injection vaccine does not protect dogs against a certain strain of street virus. In response to many inquiries, the U. S. Bureau of Animal Industry conducted experiments on dogs, using single injection vaccine made from the strain of fixed virus which originated in the Pasteur Institute of Paris, and from which commercial vaccines in this country are said to be made. The dogs were injected with different strains of street virus by the intra-ocular route. The vaccine afforded distinct protection against two different strains of street virus, and twelve among the sixteen dogs thus inoculated survived. Against a still different strain of street virus, designated B. A. I. 474, there was practically no protection afforded and only six among the thirty dogs inoculated survived. These experiments indicate the existence in this country of more than one strain of rabies street virus. Apparently there is a strain against which the single injection vaccine affords little protection; if this observation is confirmed, a vaccine that immunizes against B. A. I. 474 virus as well as against the strain heretofore encountered will be required.

THE NEED OF CALCIUM

Much has been written of late regarding the importance of appropriate fat-soluble vitamin in the metabolism of calcium in the body. Recent experimental studies on rickets have shown in striking manner how the addition of surprisingly small amounts of such sources of the vitamin in question as cod liver oil, or of far smaller quantities of potent concentrates from cod liver oil, promotes the successful deposition of lime in the bones under dietary conditions that lead to serious osseous defects if no remedial factor is furnished. Sunlight and suitable artificial irradiation also may act to facilitate the retention of calcium under certain otherwise unfavorable conditions. Amid our enthusiasm for these discoveries we are liable, however, to overlook the fact that disturbances in the mineral metabolism may be due to a deficiency of the mineral element in question quite as well as to a lack of the factor aiding mineral assimilation. This has been emphasized in a striking way by recent animal experiments of Sherman and MacLeod[3] of Columbia University. They have shown that under certain conditions of what might be termed suboptimal nutrition—conditions such as are presumably encountered in human experience—a sufficiently liberal allowance of calcium in the food is of prime importance to the optimal storage of calcium, for animals may be able to grow on diets on which the resulting calcium content of the body falls below the normal for their weight and age. In such cases, supplements of calcium in suitable forms, rather than fat-soluble vitamins, may be the determining factor in enriching the calcium depots of the organism so that they approach optimal conditions. Animals that receive little calcium in their diets lose calcium from their bodies. The drainage that pregnancy and lactation may bring about in respect to this element is shown by the lowering of the percentage of calcium in the body as the result of bearing and suckling young. Hammett[4] believes that there are sex-specific differences in the course of differential development and that they can be traced to gonadal influences. The relation of deposition of inorganic matter to bone growth by increments in organic matter and water, he finds, is different in the male than in the female. While in the one sex there is an apparent uniformity in type of growth impulse with age, in the other some factor exerts an influence on growth by ossification independently of the general stimulus to growth by increments of organic matter and water. In other words, there is apparently an independent factor for ossification in the female which is not exhibited in the male. In both sexes, however, apparently "normal" nutrition may be far from optimal when the supply of calcium is not itself optimal. Such conditions of suboptimal calcium storage are not easily detected except by elaborate analytic investigation not always possible in man. The lesson is clear: The calcium supply should be measured with liberality wherever doubt exists. Growth, pregnancy and lactation represent conditions of unusual demand that the body struggles to satisfy from one source or another. They should not be permitted to develop a hidden weakness in the organism.

GROWTH IN MENTAL MEDICINE

During the century ending with 1920, some 37,981,462 immigrants arrived in the United States, almost 70 per cent. of them in the last forty years. In these four decades, the number of persons in public institutions for the treatment of mental disease in the United States increased almost 600 per cent., or, according to Treadway,[5] from 40,942 to 232,682. The obvious conclusion is to trace a direct relation between the enormous increase in immigration and the increase in the number of patients in mental hospitals. In 1920, Pollock and Furbish found that 33 per cent. of the first admissions in seventy-one state hospitals for mental disease were foreign born patients. Of all white persons admitted to public institutions for the insane in 1910, 25.5 per cent. were foreign born. In 1920 there were 13,920,692 foreign born persons in continental United States. Less than half of these were naturalized and less than one in ten had declared their intention of becoming citizens. Our immigration laws previous to 1920, therefore, permitted an influx of immigrants who did not intend to become citizens and of many who were mentally unstable. Immigration was, of course, only one large factor filling up our asylums. While the new immigration law of 1924 may greatly reduce the rate of admissions to mental hospitals, another preventive measure, the mental hygiene movement, has become widespread, and various scientific societies have been organized to study mental problems. In his presidential address before the American Psychiatric Association, Dr. William A. White [6] reviewed in part the last thirty years of mental medicine and made a number of recommendations. He advocated that the six separate organizations now especially concerned in mental medicine unite and establish one strong national organization with permanent headquarters that would function every day in the year. The proposal is timely. Closer cooperation is needed, if for no other reason than to keep the control of the mental hygiene movement among those who know most about mental medicine.

THE ITCH

Of all of the diseases that attack mankind, none is so humiliating both in its appearance and in its contempt for caste or class, and none so awkward in its results, as that commonly called the itch. No less a figure than Napoleon I suffered with this condition, and reports are current of its spread through entire armies and social organizations. As pointed out by Dr. George Pernet,[7] the itch is undoubtedly an ancient disease. Celsus certainly recognized it and recommended sulphur mixed with liquid pitch as affording relief both to man and to cattle. It is interesting to follow Pernet in his analysis of the literature of the past and to find how close certain observers were toward determining the cause of the disease and yet failed to grasp the connection between the disease and the parasite. Moreover, the history of the discovery of pediculosis parallels that of scabies in this point. In the work of Paré and a number of other writers of his period there are references to a minute animal in connection with the itch, but these authors continue to account for the eruption by disturbances of body "humours." An English naturalist, Moufet, pointed out that the animalcule was to be found in the neighborhood of the pustules, and Hauptmann supplied a drawing of *Acarus scabiei* in 1657. Cestoni, an Italian apothecary, told in 1687 how women in Italy picked the acarus out of its burrow; and Richard Mead, who traveled in Italy during that period, taught that itch was a local disease due to a parasite and required local treatment. As is usual with medical knowledge, however, its dissemination occurred irregularly; whereas Dr. Samuel Johnson's dictionary, dated 1755, defined itch as "a cutaneous disease extremely contagious, which overspreads the body with small pustules filled with thin serum, and raised, as microscopes have discovered, by a small animal," medical writers as late as 1819 declined to accept the causal relationship. Pernet's historical investigation casts an interesting light on this disease, and affords important data for the psychologist interested in the thought processes of scientific investigation.

THE SYNTHESIS OF CHOLESTEROL IN THE BODY

Owing to the fact that it can be prepared in crystalline form, and hence presumably in a state of comparative purity, with great ease from a variety of body sources, cholesterol is early brought to the direct attention of the student of medicine. He can separate it in abundance, without skilled technic, from the brain and other nervous structures. It is readily isolated from gallstones, and thus impresses itself on the observer as having occasional pathogenic significance. Cholesterol occurs both free and as esters in the circulating blood. In fact, the compound is so widely distributed in the animal economy that it has been looked on as a never failing component of animal cells in general. Strange as it may seem to those who are impatient at the slow progress of scientific discovery, the real function of this ubiquitous higher alcohol remains to be determined. It is scarcely to be assumed that any seemingly omnipresent tissue component is devoid of some biologic use. Of late, new interest has been infused into considerations of cholesterol through the discovery that it may become "activated" by irradiation with ultraviolet rays so that it acquires antirachitic potency. Physiologists have long been curious to know whether cholesterol can be synthesized de novo in the body or whether it is one of those substances, like the vitamins, that must be supplied "ready made" with the diet. It might be supposed that an answer to the query could easily be secured by feeding experiments in growing animals subjected to a cholesterol-free diet. The difficulty heretofore has been that no regimen had been devised that was free from cholesterol and yet adequate for growth. The conventional sources of the indispensable fat-soluble vitamins all contain cholesterol, though it is well established that the latter as such does not function as a vitamin. Success in devising a sufficient cholesterol-free diet has recently been achieved, however, by Channon [1] at the Institute of Physiology, University College, London. Not only did growth on it proceed satisfactorily, but increment in size was attended with a proportionate increase in cholesterol in the body, so that the content of this substance was apparently well within normal ranges. The organism would thus seem capable of synthesizing cholesterol.

---

Value of Personality.—The most valuable asset of the physician is personality. Its influence in sickness is mental healing, and it is of greatest value when trained and directed. The methods of employing such healing are infinite, for they vary with age and sex, with race and religion, and with circumstances.—Robertson, G. M.: *Lancet* **2**:214 (Aug. 1) 1925.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Personal.—Dr. Frederick F. Russell, director of the International Health Board of the Rockefeller Foundation, New York, and Dr. Leslie L. Lumsden, U. S. Public Health Service, addressed the sixth annual conference of county health officers at Montgomery, September 8.

Changes at Andalusia.—Dr. Charles N. Leach, New York, who has been in charge of the bureau of epidemiology of the state department of health, has been placed in charge of the International Health Board Training Base for public health officers at Andalusia. Dr. Wilson G. Smillie, who has been in charge of the training base for about three years, has been transferred by the International Health Board to a post in New York.

ARIZONA

Dr. Krause Lectures.—Dr. Allen K. Krause, Baltimore, editor of the *American Review of Tuberculosis*, delivered three lectures on the pathology of tuberculosis before the Pima County Medical Society, Tucson, the last week in September, and addressed audiences at the University of Arizona and at the high school assembly hall. Dr. and Mrs. Krause also attended a number of social functions arranged by local physicians and their wives.

CALIFORNIA

Infantile Paralysis Epidemic.—The California State Board of Health reports that there were 581 cases of infantile paralysis in the state up to August 31, this year, as compared with 49 cases in the same period last year. There were 20 deaths in June and 35 in July. There were 205 cases reported in July and 200 in August.

Chirothesian Found Not Guilty.—M. T. Larkin, Los Angeles, who was arrested on a charge of practicing medicine without a license, was found not guilty after a three day jury trial. Albert Carter, special agent for the state board of medical examiners, cites this case as an exemple of the handicap of prosecuting cases with inexperienced prosecutors. The evidence showed that Larkin treated paralysis, tumors, rheumatism and kidney disease. Larkin contended he had the right to do such things in accordance with the tenets of the Chirothesian Church, of which he is a member.

CONNECTICUT

Health Exhibit at Fairs.—The state department of health reports that thousands of people have attended the health exhibits conducted by the state department of health at the county fairs throughout the state, and that they have all been given health leaflets published by the health department. The exhibit represented the activities of the whole department of health.

FLORIDA

Charged with Attempting to Bribe.—Governor Martin has issued an order, it is reported, directing Dr. William J. Buck, Jacksonville, president of the state board of medical examiners, to show cause why he should not be removed from office on a charge of soliciting a bribe of $1,000 for issuing a license to practice medicine.

Hospital News.—The Victoria Hospital property at Miami has been sold and plans have been made to improve the property by enlarging the hospital to 106 beds and the erection of a $700,000 hotel for convalescents who desire to be under medical care without entering a hospital.——Plant City recently authorized a bond issue for a $50,000 hospital building.

Personal.—Dr. John F. Bresnahan has been appointed superintendent of the Jackson Memorial Hospital, Miami. Dr. Bresnahan is a graduate of the University of Pennsylvania School of Medicine and in hospital administration at the Massachusetts General Hospital, also of the Field Medical School of the Army in which he served as major during the war.——Dr. Mark B. Herlong, health commissioner of Jacksonville, sailed for France, September 15, to represent Jacksonville at the International Congress of Cities. Dr. Herlong will then tour the continent to observe municipal activities.——Dr. Ernest C. Levy, formerly of Richmond, Va., assumed his duties as city health officer of Tampa, September 14.

IDAHO

Hospital News.—The Nazarene Sanatorium, Nampa, will conduct a campaign for funds for a new building in October. ——The hospital at Boise now being used by the Veterans' Bureau is being remodeled at a cost of about $20,000. At present there are 114 patients in the hospital.

State Medical Election.—At the annual meeting of the Idaho State Medical Association, Pocatello, September 3-5, Dr. Nathaniel R. Wallentine, Sandpoint, was elected president; Dr. Duncan L. Alexander, Twin Falls, vice president, and Dr. Joseph N. Davis, Kimberly, secretary-treasurer.

ILLINOIS

Hospital News.—The health department of Springfield has arranged to establish a municipal contagious disease hospital, which will be constructed and operated as a unit of St. John's Hospital.

New Tuberculosis Sanatorium.—With the construction of the new Madison County Tuberculosis Sanatorium nearing completion, the sanatorium board is looking about for a superintendent and general manager for the institution, a man thoroughly conversant with tuberculosis, able to manage an institution of 100 beds, a farm of 53 acres and the personnel that will be attached to the institution.

Society News.—Dr. Walter F. Seymour, for thirty-two years a medical missionary, addressed the Galesburg Medical Society at a dinner, September 15, on "The Problems and Pleasures of a Physician in China."——Dr. Evarts A. Graham, professor of surgery, Washington University School of Medicine, St. Louis, addressed the Madison County Medical Society at St. Anthony's Infirmary, Alton, October 2, on "The Treatment of Pulmonary Conditions by Surgical Means."

Mosquito Control Work.—The twelve most southern counties in Illinois are considered by the state department of health as the "malaria belt." While they represent only about 5 per cent. of the population of the state, they have about 60 per cent. of the total malaria. There was last year eighty deaths from malaria in Illinois; about forty-eight deaths, therefore, occurred in the twelve southern counties. There are three species of mosquitoes in certain regions of Illinois which transmit malaria: *Anopheles quadrimaculatus, Anopheles crucians* and *Anopheles punctipennis.* Mosquito control work was started by the state department of health in 1922 at Carbondale, and at present there are more than twelve cities conducting mosquito campaigns. The activities of communities in mosquito control this year has been greater than in all previous years. Communities engaged in mosquito campaigns of various kinds include Carbondale, Murphysboro, Belleville, West Frankfort, Gorham, Ravinia Park, Winnetka, Kenilworth, Glencoe, Evanston and Highland Park. The Chicago Sanitary District, the North Shore Sanitary District and several Cook County organizations cooperate in antimosquito work.

Chicago

Society News.—The regular meeting of the Chicago Society of Industrial Medicine and Surgery will be held at the Great Northern Hotel, October 5, at 8:30. Dr. Emile C. DuVal will speak on "Diathermy in the Treatment of Industrial Cases."

Another Swindler.—Information has been received that a man giving the name of Russell Palefano has called on physicians in Chicago presenting himself as a patient with venereal disease, paying for treatment by means of a large check and asking for the difference in cash. His check has turned out to be worthless.

Hospital News.—Dr. Frank Billings will lay the cornerstone of the Albert Billings Memorial Hospital at the University of Chicago, October 3, and Max Mason, Ph.D., president of the university, will preside at the ceremonies; Dr. Henry A. Christian, professor of medicine, Harvard University School of Medicine, Boston, will deliver an address.——The four-story building on Cambridge Avenue, formerly used by the Grant Hospital for a nurses' home, has been sold and will be remodeled for hotel purposes.

Anniversary of Chicago Surgical Society.—At the twenty-fifth anniversary dinner of the Chicago Surgical Society, October 2, Hotel Sherman, the speakers were charter members of the society. Dr. Edward Wyllys Andrews' subject was "Albert J. Ochsner—Our Colleague and Friend"; Dr. Weller Van Hook spoke on "The Advance in Surgery in Chicago During the Last Twenty-Five Years"; Dr. Lewis L. McArthur, "The Surgical Profession in Chicago in the Last Twenty-Five Years," and Dr. Arthur Dean Bevan, "The Teaching of Surgery in Chicago in the Last Twenty-Five Years." Among former eminent surgeons of Chicago who were charter members were Drs. Senn, Fenger, Murphy, Ochsner and John E. Owens.

KANSAS

Infantile Paralysis.—Three cases of infantile paralysis were reported near Cunningham, September 14.

Personal.—Dr. Arthur D. Gray has been appointed in charge of the new urologic clinic which was opened by the city health department at the city hall, Topeka, September 16.

Medical School Exhibit at Fair.—University of Kansas School of Medicine, Rosedale, arranged a display of 150 pathologic specimens from the school's museum for exhibition at the Free Fair at Topeka A staff of attendants from the medical school, comprising Drs. Harry R. Wahl, dean, and Ferdinand C Helwig of the faculty and others, were in charge of the exhibit. Among the specimens were tuberculosis of the lung, kidney disease, gallstones, heart disease and microscopic studies of cancer.

KENTUCKY

Personal.—Dr. Hervey B. Scott has been reappointed a member of the department of neurology and psychiatry at the City Hospital, Louisville.——Dr. Martin J. Sauter has been appointed a member of the board of health of Newport to succeed Dr. George Brown.——Dr. William A. Krieger, Newport, has been appointed health commissioner of that city, to succeed Dr. John Todd, resigned, who has been health officer for the last sixteen years. Dr. Todd's resignation becomes effective November 1.——Dr. Edward P. Guerrant, Winchester, has been appointed physician to the Kentucky Wesleyan College.

Smallpox Survey.—The state board of health investigated the reports of smallpox in ninety-five of the 120 counties in the state and found that there had been 1,700 cases in the fiscal year ending June 30, 1925, of which 150 were severe and eight fatal. The survey showed also that about 30 per cent. of the school children of the state had been successfully vaccinated against smallpox, the number of vaccinated ranging from 1 per cent. of the school children in some counties to about 100 per cent. in others. The code of health of Kentucky contains definite regulations which require vaccination as a prerequisite to attendance at school. The state board, September 11, therefore declared an emergency to exist and called on county and city boards of health and boards of education to enforce the vaccination laws as to the eligibility of unvaccinated children to attend school.

LOUISIANA

Appointments to Board of Health.—At the meeting of the council of Alexandria, September 8, a resolution was adopted providing for the appointment of a city board of health, and the following members were appointed: Drs. Joseph A. Packer, Leonard D. Gremillion, G. M. Graham Stafford, Mayor J. F. Foisy and Irvin McGinis.

Society News.—Dr. William F. Bay, U. S. Veterans' Bureau Hospital No. 27, addressed the Eighth District Medical Society, Pineville, September 15, on "Principles of Rest in the Treatment of Tuberculosis," and Dr. George L. Drouin, Mansura, a member of the state house of representatives, spoke on action taken by the last legislature of interest to the medical profession.

Personal.—Dr. Joseph O. Weilbaecher, New Orleans, has been appointed physician to the police department, to succeed Dr. Leonard C. Chamberlain.——Dr. Victor C. Smith has been appointed head of the department of ophthalmology at the new Southern Baptist Hospital, New Orleans.——H. W. Conner, Richmond, Va., has been appointed full-time sanitary inspector for St. James Parish.——Dr. Allen B. Jemison, Macon, Ga., newly appointed director of the health unit of DeSoto Parish, arrived in New Orleans, September 25, to assist the state department of health in maternity and infancy work for one month.——Dr. E. Aitken Segar, of the Imperial College, Port of Spain, Trinidad, is in Louisiana observing public health methods.

Record Enrolment at Tulane.—Tulane University of Louisiana School of Medicine, New Orleans, opened its annual session with the largest freshman class in years. The pressure for admission into the medical school was such, it is reported President Dinwiddie said, that several hundred students were refused admission. The following seventeen new members have been added to the faculty of the undergraduate school of medicine: James O. Foley, Ph.D., instructor in anatomy; Drs. John D. Humber, instructor in anatomy; Edmond L. Faust, instructor in clinical obstetrics; Arthur Caire, instructor in clinical obstetrics; Curtis H. Tyrone, instructor in clinical obstetrics; Emmett L. Irwin, instructor in clinical surgery; Rodger J. B. Hibbard, instructor in pathology and bacteriology; Stuart A. Wallace, instructor in pathology and bacteriology; Shirley Carlton Lyons, assistant in anatomy; Earl Z. Browne, assistant in medicine and in the laboratories of clinical medicine; Russell C. Pigford, assistant in medicine and in the laboratories of clinical medicine; Louis V. J. Lopez, assistant in clinical psychiatry; Euclid B. Gill, assistant in pediatrics; George L. Hardin, assistant in clinical ophthalmology; Frank L. Loria, assistant in clinical surgery; James L. Smith, assistant in pathology and bacteriology; Stella M. A. Leche, B.Sc., student assistant in biochemistry.

MARYLAND

Society News.—At the regular meeting of the Baltimore County Medical Association, September 16, at the Medical and Chirurgical Faculty Building, Baltimore, Dr. Edward A. Looper gave an illustrated lecture on "The Diagnosis and Treatment of Tuberculosis of the Larynx."

Dr. Halstead's Work to Be Published.—An edition of the complete works of Dr. William S. Halstead, late professor of surgery at Johns Hopkins, is under way, edited by Dr. Walter C. Burket, Evanston, Ill., in two volumes. As an introduction to the edition, a biographic sketch of Dr. Halstead is being written by Dr. William H. Welch, director, Johns Hopkins School of Public Health and Hygiene, who is the oldest living associate of Dr. Halstead. Dr. Halstead was associated with Johns Hopkins University from 1881 until his death, September, 1922.

Expansion of Johns Hopkins Hospital.—According to statements issued by the Johns Hopkins Half Century Committee, development extending over ten years and involving an expenditure of $13,000,000 is planned for the Johns Hopkins Hospital. The plan calls for additional endowment of the hospital and school for nurses, building and endowment of new medical and surgical clinics, an institute for the study and treatment of diseases of the nervous system, a convalescent branch of the hospital, a central medical library and a special endowment to aid persons of moderate means. The quarters of the medical and surgical wards have remained essentially the same since 1889, when the hospital was opened. A part of the quarters used by the nurses has been assigned to the Wilmer Institute; even prior to this change, many nurses had to live outside the hospital. Special work in nervous diseases is needed to supplement the work of the Henry Phipps Psychiatric Clinic. The Half Century Committee hopes to obtain in October from Baltimore $1,500,000 for the support of the university and the hospital. The most pressing need of the hospital is endowment for work for the sick children of Baltimore. Since almost all of the children cared for are from Baltimore, the hospital must depend primarily on Baltimore to support this work.

MASSACHUSETTS

Lectures on Mental Health of Children.—The Boston University School of Education announces a series of fifteen practical lectures on "Understanding the Child and His Needs," to be given on Tuesday evenings at 8 o'clock at 688 Boylston Street, Boston, beginning September 29. The course will be given in cooperation with the Massachusetts Society for Mental Hygiene and discussions will follow each lecture. Credit of one point will be given toward the degree of bachelor of science in education or the degree of master of education. In the second semester a course of lectures will be given on the "Physical Life of the Child."

MICHIGAN

Police and Fire Surgeons.—The annual meeting of the National Association of Police and Fire Surgeons will be held in Grand Rapids, October 6-7. City physician, Allison H. Edwards, is chairman of the local committee on arrangements. A subject which will receive attention at this meeting is the proposal to standardize the physical requirements of civil service employes, especially of policemen and firemen in large cities. Proposed standards will be submitted to this convention for definite action. There are about 150 members in this association which is now four years old. Previous conventions have been held in Philadelphia, Atlantic City and New York.

Society News.—Dr. William F. Wild, field director of the American Society for the Control of Cancer, addressed a public meeting under the auspices of the Wayne County Medical Society, Detroit, September 15, on cancer.——Dr. Hugh Cabot, dean and professor of surgery, University of Michigan Medical School, Ann Arbor, will address the Wayne County Medical Society, October 5, on "Diagnosis and Methods of Attack on Tumors of the Kidney."——Henry F. Vaughan, D.P.H., Detroit, city commissioner of health, addressed the East Side Physicians' Association, October 1, at the Whittier Hotel on "The Relationship of the Board of Health to the General Practitioner."

Heart Disease in Michigan.—The August *Bulletin* of the state department of health says that heart disease was the cause of 13.1 per cent. of all deaths in Michigan in 1924, a rate of 159.2 deaths per hundred thousand of population. A comparison of the rates for heart disease in Michigan and in the U. S. registration area as a whole for eight years ending with 1922 shows that the Michigan rate was continuously higher than that of the registration area. About 60 per cent. of the deaths from organic heart disease occur after the age of 65; the last census showed that 5.3 per cent. of the people of Michigan were at least 65 years of age, whereas in 1870 only 2.7 per cent. of the people had reached that age. The health department points out that in the last half century the population of the state has changed so that it has twice as many candidates for heart disease as formerly, and that the relatively slight increase in the rate is, therefore, no cause for apprehension.

New Whooping Cough Regulations.—The department of health of Detroit notes in its bulletin that there were seventy deaths from whooping cough in that city this year up to September 1 as compared with forty-six deaths in the same period last year. New regulations have therefore been adopted to control the whooping cough situation, one of which is that whooping cough clinics will be discontinued by the department of health; physicians of the health department will not send whooping cough patients to the department clinic for diagnosis and treatment but refer them whenever possible to private physicians or to the city physician. The isolation period for whooping cough is considered as four weeks from the date of the report of the disease. The patient and susceptible contacts during the period of isolation shall be confined to the premises which include the home and rear yard only, but susceptible contacts (these are considered children of preschool and grade school age who have not previously had whooping cough) may be transferred to the home of adult friends for observation during the period of isolation.

MISSISSIPPI

Personal.—Dr. John D. Spelman, medical superintendent of the Touro Infirmary, New Orleans, recently surveyed the Natchez Hospital, Natchez, for the purpose of making recommendations regarding standardization.——Dr. Charles P. Coogle has been elected officer in charge of the Leflore County health unit.

MISSOURI

Infantile Paralysis.—Since March 1 there had been reported forty-four cases of infantile paralysis in Kansas City and fourteen deaths. However, in the two weeks ending September 21 only one new case had been reported.

Society News.—Dr. Joseph P. Costello addressed the St. Louis Medical Society, September 22, on "Roentgen Ray of the Thymus in Infantile Eczema," and Dr. Willard Bartlett on "What Course to Pursue When Confronted by a Goiter Patient with a Second Surgical Lesion."——At the general meeting of the St. Louis Medical Society, September 29, Dr. Randall S. Tilles gave a lantern slide demonstration of "An Early Case of Hydatiform Mole." Dr. Joseph E. Stewart spoke on "Kohler's Disease of Tarsal Scaphoid."

Grand Jury Investigation of Diploma Mill Charges.—The Jackson County Grand Jury, sitting at Kansas City, will investigate the Missouri medical diploma mill scandal. When the grand jury convened, September 22, Judge Nelson E. Johnson gave instructions to indict persons found guilty of fraud in obtaining licenses or diplomas. The judge said, in part, "There have been many charges of late that men have received diplomas to practice medicine in this state who are not entitled to receive them, and that men have received licenses to practice medicine in this state who are not entitled to receive licenses. If these charges are true, it is hard to conceive of a greater crime, because into the hands of these men fall the woes and the ills of our citizens."

New State Board of Health.—Following his request for the resignation of all members of the state board of health, Governor Baker has appointed the following physicians members of the new board: Dr. William A. Clark, Jefferson City; Drs. James Stewart and Willard Bartlett, St. Louis; Dr. Herbert A. Breyfogle, Kansas City; Dr. Elmer T. McGaugh, Richmond; Dr. Herman S. Gove, Linn, and Dr. Homer L. Kerr, Crane. In his announcement, the governor stated that he desired Dr. William Clark to be elected president of the board and Dr. James Stewart, secretary, at the meeting of the board held in Jefferson City, September 23. Dr. Clark was formerly president of the state board of health from 1917 to 1921 and last year was president of the Missouri State Medical Association. The members of the old board who were reappointed to the new board of health are Drs. Stewart, Kerr and Gove.

MONTANA

Resolution on Medical Taxes.—At the last meeting of the Medical Association of Montana, Lewistown, resolutions were passed declaring unjust the war tax of $3 against physicians under the Harrison Narcotic Law, the tax on traveling expenses necessary for attendance at medical meetings and the tax on expense of postgraduate study.

NEW JERSEY

Chiropractor Convicted.—It is reported that John H. Conover, Jersey City, was sentenced, September 22, to three months in jail on a charge of practicing medicine without a license. This is said to be the third time that Conover has been convicted on similar charges.

NEW YORK

Sanatorium for Actors.—The National Vaudeville Artists, Inc., announced, September 23, the purchase of a 50-acre estate near Saranac Lake to be used as a sanatorium for patients which are supported by that organization. The buildings will be remodeled, it is reported, to make the institution available to all branches of the theatrical profession.

Society News.—The Westchester County Medical Society held its September meeting at the Grasslands Hospital, White Plains, and in addition to an inspection of this 500-bed hospital were addressed by Dr. Robert W. Gover, New York, on "Infantile Paralysis," followed by a report by Dr. Leo J. Schweiger of the resident staff, on eleven cases of this disease recently treated in this hospital.

Nurses Dismissed.—The forty-seventh graduate nurse was dismissed from duty at the Albany Hospital, Albany, September 13, it is reported, for conduct considered in violation of hospital regulations The board of governors announced new rules for nursing, August 8, which specified in part that nurses should not have a choice of day or night duty, of the class of patient, or whether they should care for one or more patients and the rate of pay was fixed in accordance with the number of patients cared for. The dismissals, it is reported, arose out of opposition to these rules.

Hospital Experiment with Mental Cases.—The report of the Winifred Masterson Burke Relief Foundation for 1923-1925 details work done in treating selected psychoneurotic patients by introducing them into the general group of patients at the convalescent home and in the general régime at the Burke Foundation A report on the progress of about 500 cases will be forthcoming. The foundation maintains a convalescent home at White Plains and other branch homes. The report the Grant Hospital for a nurses' home, has been sold and will be remodeled for hotel purposes.

Anniversary of Chicago Surgical Society.—At the twenty-fifth anniversary dinner of the Chicago Surgical Society, October 2, Hotel Sherman, the speakers were charter members of the society. Dr. Edward Wyllys Andrews' subject was "Albert J. Ochsner—Our Colleague and Friend"; Dr. Weller Van Hook spoke on "The Advance in Surgery in Chicago During the Last Twenty-Five Years"; Dr. Lewis L. McArthur, "The Surgical Profession in Chicago in the Last Twenty-Five Years," and Dr. Arthur Dean Bevan, "The Teaching of Surgery in Chicago in the Last Twenty-Five Years." Among former eminent surgeons of Chicago who were charter members were Drs. Senn, Fenger, Murphy, Ochsner and John E. Owens.

KANSAS

Infantile Paralysis.—Three cases of infantile paralysis were reported near Cunningham, September 14.

Personal.—Dr. Arthur D. Gray has been appointed in charge of the new urologic clinic which was opened by the city health department at the city hall, Topeka, September 16.

Medical School Exhibit at Fair.—University of Kansas School of Medicine, Rosedale, arranged a display of 150 pathologic specimens from the school's museum for exhibition at the Free Fair at Topeka. A staff of attendants from the medical school, comprising Drs. Harry R. Wahl, dean, and Ferdinand C. Helwig of the faculty and others, were in charge of the exhibit. Among the specimens were tuberculosis of the lung, kidney disease, gallstones, heart disease and microscopic studies of cancer.

KENTUCKY

Personal.—Dr. Hervey B. Scott has been reappointed a member of the department of neurology and psychiatry at the City Hospital, Louisville.——Dr. Martin J. Sauter has been appointed a member of the board of health of Newport to succeed Dr. George Brown.——Dr. William A. Krieger, Newport, has been appointed health commissioner of that city, to succeed Dr. John Todd, resigned, who has been health officer for the last sixteen years. Dr. Todd's resignation becomes effective November 1.——Dr. Edward P. Guerrant, Winchester, has been appointed physician to the Kentucky Wesleyan College.

Smallpox Survey.—The state board of health investigated the reports of smallpox in ninety-five of the 120 counties in the state and found that there had been 1,700 cases in the fiscal year ending June 30, 1925, of which 150 were severe and eight fatal. The survey showed also that about 30 per cent. of the school children of the state had been successfully vaccinated against smallpox, the number of vaccinated ranging from 1 per cent. of the school children in some counties to about 100 per cent. in others. The code of health of Kentucky contains definite regulations which require vaccination as a prerequisite to attendance at school. The state board, September 11, therefore declared an emergency to exist and called on county and city boards of health and boards of education to enforce the vaccination laws as to the eligibility of unvaccinated children to attend school.

LOUISIANA

Nurses Dismissed.—The forty-seventh graduate nurse was dismissed from duty at the Albany Hospital, Albany, September 13, it is reported, for conduct considered in violation of hospital regulations. The board of governors announced new rules for nursing, August 8, which specified in part that nurses should not have a choice of day or night duty, of the class of patient, or whether they should care for one or more patients and the rate of pay was fixed in accordance with the number of patients cared for. The dismissals, it is reported, arose out of opposition to these rules.

Hospital Experiment with Mental Cases.—The report of the Winifred Masterson Burke Relief Foundation for 1923-1925 details work done in treating selected psychoneurotic patients by introducing them into the general group of patients at the convalescent home and in the general régime at the Burke Foundation. A report on the progress of about 500 cases will be forthcoming. The foundation maintains a convalescent home at White Plains and other branch homes. The report shows, says the New York *Times,* that in all 49,154 patients have been treated at the White Plains institution since it opened in 1915.

New York City

Personal.—Dr. Martin L. Janes has been appointed visiting hematologist to the Manhattan State Hospital, Wards Island. ——Dr. Royal S. Copeland has been elected president of the newly organized Fordham National Bank at Jerome Avenue and Fordham Road.

Dr. Basil Graves to Lecture.—The New York University and Bellevue Hospital Medical College announces that beginning October 5, Dr. Basil Graves, London, England, will give three courses of two weeks each in slit lamp microscopy of the eye at that college. Further information can be obtained from the secretary, 338 East Twenty-Sixth Street.

Trust Funds of Academy of Medicine.—The annual report of the New York Academy of Medicine for 1924, which has just been received, shows that the trust funds of the academy amount to $761,268.97. The number of separate funds specified is twenty-five, ranging in amount from $100 up to the "general permanent fund" (the income of which is to be used for advancing medical science) of $412,680.71. During 1924 six other organizations maintained offices in the academy buildings, the Medical Society of the State of New York, the Medical Society of the County of New York, the Society for Relief of Widows and Orphans of Medical Men, the Physicians' Mutual Aid Association, the Hospital Information Bureau, and the Committee on Dispensary Development; thirty-eight organizations held their meetings in the academy buildings, and accommodations free of charge were granted to other associations, committees and lectures.

NORTH CAROLINA

Personal.—Governor MacLean announces the appointment of Dr. William A. Rogers, Franklin, as a member of the board of trustees of the State School for Deaf at Raleigh. ——Dr. Verne S. Caviness, Raleigh, has announced his retirement from the Mary Elizabeth Hospital staff and Diagnostic Clinic.

District Society to Conduct Clinics.—The annual session of the Tenth District Medical Society was held at Canton, September 23, under the presidency of Dr. Louis G. Beall, Black Mountain. Dr. William de B. MacNider, president, North Carolina Medical Society, the guest of honor, spoke on "The Value of Certain Drugs in Hypertension." Dr. Francis M. Davis was elected president and Dr. John LeBruce Ward, Asheville, secretary. It was decided to conduct a clinic in each of the smaller cities of the district during the year.

Tuberculosis Conference at Oteen.—A conference called by the U. S. Veterans' Bureau will be in session for two weeks at Oteen, beginning September 23; among the lecturers in attendance are Drs. Roy D. Adams, Washington, D. C.; Henry Kennon Dunham, Cincinnati; John D. MacRae, Asheville, N. C.; Nathan Barlow, dean, U. S. Veterans' Postgraduate School for Tuberculosis; Lieut.-Col. Earl H. Bruns, M. C., U. S. A., and Dr. Edgar O. Crossman, Washington, D. C. More than eighty physicians of the Veterans' Bureau are attending.

Society News.—The Edgecombe County Medical Society held a joint open session with the Parent-Teachers' Association in Greenville, N. C., September 9, and were addressed by Dr. Charles O'H. Laughinghouse of the state board of health on public and private health interests of school children.——The Wake County Medical Society recently endorsed the proposal of the Wake County Board of Health to launch an infancy and maternity hygiene ward in order to secure a standard training for midwives with proper professional instruction.

OHIO

Society News.—Dr. William J. Mayo, Rochester, Minn., was the guest of honor, September 18, at the Medical Education Day held by the Academy of Medicine of Cleveland for physicians of the fifth district of the state association.

Personal.—Dr. I. C. Riggin, Richmond, Va., recently state epidemiologist of Virginia, assumed the duties of county health commissioner of Lorain County, October 1, succeeding Dr. William A. McIntosh, who will go to Siam for the International Health Board.

Sandusky Typhoid a Milk Epidemic.—It is reported that the state director of health, Dr. J. E. Munger, recently returned from an investigation of the typhoid epidemic at Sandusky, where he found that sixty cases had been reported, all of which had been using milk from the same dairy. The dairy owner was directed to pasteurize his milk supply and prevented from delivering milk until that had been done.

PENNSYLVANIA

Typhoid at York.—About twenty cases of typhoid fever were recently reported in or near the city of York; eight new cases were reported, September 12.

Memorial Opened.—The new Lewes Mason Memorial Building of the Chester County Hospital, was opened to inspection by the public, September 19. The building is the gift of Pierre Du Pont of Wilmington and Longwood, and is dedicated to the memory of Lewes Mason, a ward of Mr. Du Pont, who died during the pandemic of influenza.

Charities Association Meeting.—The Public Charities Association of Pennsylvania will hold the fall meeting of the board of directors in Bethlehem, October 23. There will be a luncheon at the Hotel Bethlehem under the joint auspices of the Central Council of Social Service and the Woman's Club of Bethlehem. Dr. Charles H. Frazier, Philadelphia, will be the toastmaster and Dr. William L. Estes, Bethlehem, a director of the association, will preside.

Personal.—Dr. Joseph C. Bloodgood, Johns Hopkins University Medical School, Baltimore, addressed the Lycoming County Medical Society, Williamsport, September 11, on "The Diagnosis of Breast and Bone Tumors."——Dr. Harvey R. Bauman, Hawley, and his wife, Dr. Ella G. Bauman, formerly of Allentown, will sail, October 3, for India, to take up work as medical missionaries.

Joint Meeting at Valley Forge.—Physicians from the medical societies of Chester, Delaware, Schuylkill and Berks counties held a joint meeting at Valley Forge recently at the invitation of the Chester County Medical Society. Dr. William T. Sharpless, West Chester, councilor of the Third District, presided, and among the speakers were Dr. Wilmer Krusen, health commissioner of Philadelphia; Dr. Ira G. Shoemaker, president-elect of the Medical Society of the State of Pennsylvania, and Dr. John Norman Henry, president of the state society. Following the meeting a luncheon was served at the Valley Forge Inn.

Philadelphia

Hospital News.—Mayor Kendrick turned the first sod in starting the construction of the new $4,000,000 Philadelphia General Hospital at Thirty-Fourth and Pine streets, September 22.

Society News.—At the first fall meeting of the Women's Auxiliary of the Philadelphia County Medical Society, in the Bellevue-Stratford Hotel, September 17, Dr. Charles N. Sturtevant, Frankford, spoke on "The Care of Children."

National Medical Congress at Sesquicentennial.—The Philadelphia County Medical Society is making plans for a National Medical Congress in this city next year during the sesquicentennial celebration. Invitations will be sent to national and international medical organizations to meet in Philadelphia simultaneously. An international medical congress was held in Philadelphia in 1876 during the celebration of the centennial.

Dr. French Goes to University of Pennsylvania.—Dr. Harley E. French has been appointed assistant professor of anatomy in the University of Pennsylvania School of Medicine, according to the announcement made by Josiah Penniman, LL.D., president and provost, at the opening exercises, September 25. Dr. French was professor of anatomy and dean of the School of Medicine of the University of North Dakota for fourteen years and professor of physiology and anatomy at the University of South Dakota for four years.

Opening Session at Jefferson Medical College.—The one hundred and first annual session of Jefferson Medical College, Philadelphia, was opened, September 23, with an assembly of the faculty, officers of the college and the student body in the new hospital building. The freshman class, which, it is reported, numbers this year 175, was selected from more than 2,200 applications for admission. William Potter, president of the board of trustees, and formerly U. S. minister to Italy, Dr. Ross V. Patterson, and Dr. Fielding O. Lewis, professor of laryngology, gave addresses. Additions to the faculty announced were Dr. Pascal Brooke Bland, professor of obstetrics, Dr. William M. Sweet, professor of ophthalmology, and Dr. Edward A. Strecker, professor of nervous and mental diseases.

TENNESSEE

Personal.—Dr. Haven Emerson, New York, spent September 14-16 in Memphis for conferences in connection with the survey of hospitals and other health agencies in this city.

Hospital News.—The Mountain View General Hospital, Erwin, was recently opened.——The new building of the King's Mountain Memorial Hospital, Bristol, will be opened, October 7.

Medical Arts Building.—The Tennessee Independent Order of Odd Fellows will erect a twelve-story medical arts building costing $800,000, at 119 Seventh Avenue, North, Nashville. There will be a garage in the basement for tenants in the building which will accommodate ninety cars. Work on the structure will start as soon as the old building on this site can be removed.

TEXAS

Hospital News.—Dr. A. B. Garland has awarded the contract for a $50,000 hospital building at Cumberland and Wichita streets, Vernon, which will bring the total bed capacity of the hospital to 125.

Personal.—Dr. Charles W. Castner, September 1, assumed the duties of superintendent of the State Hospital for the Insane at Wichita Falls.——Meyer Bodansky, Ph.D., associate professor of biological chemistry, University of Texas Department of Medicine, Galveston, has been granted a leave of absence for 1925-1926 to accept a temporary appointment in the department of chemistry of Stanford University.

Proposed Health Unit for Amarillo.—The Potter County Medical Society has appointed a committee, comprising Drs. James R. Wrather, Willis H. Flamm and Martin L. Fuller, to investigate a report on the proposal of the Rockefeller Foundation to establish a health unit in Amarillo. The financial arrangement will be that the state health department, the city of Amarillo, Potter County and the Rockefeller Foundation pay appropriate portions of the expense of the unit.

Enforcing the Medical Practice Act.—The secretary of the State Medical Association of Texas writes that the association is joining heartily in the campaign of the state board of medical examiners to enforce the Medical Practice Act, and that they are being successful. The chief offenders against the Medical Practice Act in Texas, the secretary says, are chiropractors. The Medical Practice Act now has a clause providing for injunction against chronic violators of this law, which is being applied as soon as possible in each case. Prosecutions are now pending in a large number of counties in the state and complaints are being filed almost daily.

WASHINGTON

Society News.—Dr. Carl E. Koenig addressed the Puget Sound Academy of Ophthalmology and Otolaryngology, September 15, at the Virginia Mason Hospital, Seattle, on "The Value of the Granger Line in Diagnosis of Disease of the Sphenoid Sinus."——The general meeting of the King County Medical Society, September 14, was held in conjunction with the Surgical Section. A motion was carried for the appointment of a committee to work in cooperation with the commissioner of health of Seattle in matters that pertained to the health of the city. Dr. Erestus T. Hanley, commissioner of health of Seattle, addressed the society.

PHILIPPINE ISLANDS

Outbreak of Cholera in Manila.—There were nineteen cases of cholera in Manila reported between September 1 and September 27; fourteen of them were fatal. There were also in this period forty-two other suspected cases of cholera. The health department administered anticholera vaccine, September 27, it is reported, to 4,000 persons. A later report gives the number of new cases on September 29 as twenty and the number of deaths on that day as six.

CANADA

Gifts to Hospital.—Mr. A. R. McNichol, Winnipeg, has donated $250,000 to the Winnipeg General Hospital, and $100,000 to the Children's Hospital, for endowment purposes to be used in such manner as the board may see fit.

Physicians in Provincial Parliament.—Four of twelve medical candidates for the provincial parliament of Nova Scotia were successful at the recent elections. They are Drs. Wallace N. Rehfuss, Bridgewater; John A. MacDonald, St. Peters; John L. MacIsaac, Antigonish, and Benjamin A. LeBlanc, Arichat.

Hospital News.—The Ste. Agathe Sanatorium, Quebec, was ready for the reception of patients, September 1; the capacity now is 210 beds. The old main building will be set aside for private patients; there are no wards of more than eight beds. The hospital has been taken over from the provincial government by the Laurentian Sanatorium Association.

No Medical Graduates This Year from Queens University.—As a result of changing from five to a six year course, there were no graduates in medicine from the Medical Faculty of Queens University, Kingston, Ont., for the year 1925. One hundred and seventeen students received the degree of M.B. from the University of Toronto Faculty of Medicine in June. There were twenty-one graduates from the University of Western Ontario Medical School, London.

Scholarship Prizes and Fellowships.—At the June commencement of the University of Toronto Faculty of Medicine, Toronto, J. H. Couch was awarded the George Brown Memorial Fellowship; C. E. Knowlton, the George Armstrong Peters Scholarship; William A. Costain, the Reeve Prize; C. E. Knowlton, the Chappell Prize; C. H. Best, the J. J. Mackenzie Prize; Miss C. H. Craw, the James H. Richardson Fellowship, and C. H. Best, the Ellen Mickle Fellowship.

Personal.—Dr. Arthur C. Jost, provincial health officer of Nova Scotia, has been appointed deputy registrar general.——Dr. Joseph Guerard, Quebec, has been appointed medical director of the Laval Hospital, St. Foy, Quebec, to succeed Dr. Odilon Leclerc.——Dr. James W. Crane, London, Ontario, has been elected president of the Harvey Club to succeed Dr. Hibbert W. Hill, who resigned when he accepted the position of professor of public health at the University of British Columbia.——Dr. F. May Whittaker, London, England, has arrived in Winnipeg to assume the duties of superintendent of Grace Hospital of the Salvation Army. Dr. Whittaker served four and a half years in France during the World War.

Banting Research Foundation.—The endowment of the Banting Research Foundation will be invested under the direction of the board of governors of the University of Toronto, who will act as trustees. They will pay to the governing body of the foundation the annual income from the endowment for disbursement. The present board of the foundation consists of Sir Robert Falconer, Lieut.-Col. R. W. Leonard, Dr. William E. Gallie, Prof. J. G. Fitzgerald, Prof. V. E. Henderson, Rev. Canon H. J. Cody, O. S. Macdonald and John W. Rogers. The *Canadian Medical Association Journal* says that the income from $500,000 is considered sufficient to support the foundation for some years; it is proposed to make the funds available to assist research workers either working independently or in any other university in Canada. The foundation has been established with a view to discovering means for the prevention and cure of diseases which at present are considered incurable. Neither Dr. Banting nor Dr. Best will receive anything from the foundation; they have renounced all rights to any income from royalties or patents from the sale of insulin.

GENERAL

Medical Bookplates.—Mr. H. M. Barlow, secretary of the Royal College of Physicians, Pall Mall East, S.W.1, London, England, is making a collection of bookplates of medical interest for the library of the college. Physicians who possess bookplates will aid the collection by sending copies to Mr. Barlow.

Dr. Howard Rescued.—Dr. Harvey J. Howard, head of the ophthalmologic department, Peking Union Medical College, Peking, China, who was captured by bandits, July 20, in Manchuria, and has since been held for ransom, has been released, it is reported, following a battle between his captors and Chinese troops.

Award of Prize of Roentgen Ray Society.—At the annual meeting of the American Roentgen Ray Society, Washington, D. C., September 22, the committee decided to award the $1,000 Leonard Prize in two portions of $600 and $400, and to award the former to Drs. Evarts A. Graham, Glover H. Copher and Warren H. Cole, all of St. Louis, for their work on cholecystography (The Journal, Jan. 3, 1925, p. 14, and April 18, 1925, p. 1174) and the latter portion to G. Failla, New York, for his work on radon.

American Student Health Association.—The next meeting of this association will be in New York City, December 29-30. The meeting has been arranged to coincide with that of the National Collegiate Athletic Association at the Hotel Astor, and the program of the first session so as to interest directors of athletics and coaches. There will be four sessions in all. In arranging the program, the secretary, Dr. Warren E. Forsythe, University of Michigan, Ann Arbor, requests that those who know of interesting work in this field communicate with him.

Public Health in Palestine.—The president of the American Branch of the Palestine Foundation announced, September 26, that American Jews would be called on to contribute $3,000,000 in the next year for the development of the Jewish homeland in Palestine, and that during the four years of its existence the fund has expended there over $8,000,000, of which two-thirds has come from the United States. Among the items in its budget for the coming year is one of $200,000 for public health work to continue the campaign against malaria and other diseases.

Personal.—Dr. Theobald Smith, director of the department of animal pathology of the Rockefeller Institute, has been nominated president of the International Anti-Tuberculosis Union. At the recent meeting in Geneva it was decided to hold the next international conference at Washington, D. C., from September 30 to October 2, 1926.——Vernon Kellogg, Sc.D., of the National Research Council, was made Commander of the Order of Leopold by King Albert while in Belgium recently where he attended the meeting of the International Research Council at Brussels.

Schools Teaching Oral Hygiene.—The Department of the Interior reports that ten educational institutions now give courses for training oral hygienists, and that twenty-one states license the oral hygienists to practice while other states permit their teaching oral hygiene. The course in most cases extends over one academic year and consists in acquiring the technic of the examination and cleaning of teeth and other minor dental operations. The Department of the Interior considers this a new occupation which has arisen out of the recent development in preventive medicine.

American Stomatological Association.—For the first time in the history of the International Stomatological Association, the American Stomatological Association was admitted to membership at the recent Paris meeting. The international association, which now has twenty-eight countries represented, is a medical association which fosters the idea that the medical degree, or as it is called in some other countries the medical requirement, should be legally established for the practice of dentistry throughout the world. Alfred J. Asgis, D.D.S., New York, was appointed adjunct secretary general of the American Association, and a corresponding member of the Italian Stomatological Federation.

League Adopts Plan to Replace Opium Crop.—The League of Nations Assembly Commission adopted, September 23, the project of sending a commission to Persia to study the possibility of replacing the cultivation of opium in that country by other agricultural products and recommended to the Budget Commission the allotment of 200,000 francs for this work. This plan was sponsored last year by the American delegation to the opium conference. An investigating committee will probably start for Persia in the spring, and there is a possibility that the commission may go to Turkey for similar studies; Serbia has expressed a willingness to discuss the possibility of changing her crops also.

Classification of Dental Colleges.—According to the *Atlantic Medical Journal,* the Dental Educational Council of America has established a predental year for 1926 as one requirement for Class A rating of dental colleges. The "two-three graduate plan of dental education" now under trial proposes two years of work in a liberal arts college followed by three years in a dental school for a degree for the general practitioner while the various dental specialties can be taught in full year graduate courses to those who elect them. The Dental Educational Council recently issued a list of dental schools of the United States: there were twenty-four in Class A, fourteen in Class B, two in Class C, and the rating of three was postponed.

Building Code for Hospitals.—A committee, representing organizations of architects, engineers, insurance companies and others interested in safety, has drawn up a building code to safeguard the lives of patients and other occupants of hospitals, sanatoriums and corrective institutions. The code awaits the acceptance of all of the interested organizations when, according to *Hospital Progress,* it will be recommended for minimum use in the development of legislation concerning the construction and management of hospitals. The code emphasizes substantial construction, fire prevention and good management. The committee recommends that existing hospital buildings should be made to conform to the standards for new buildings as far as possible.

Proposed Registration Area for Morbidity Reports.—The last Congress ratified an international treaty providing that each signatory power shall publish statistics of communicable and preventable diseases. According to Surgeon General Cummings reports of communicable diseases at present are provided by state and local health officers with very little share in the expense by the federal government. Congress failed to approve an estimate of $4,000 to assist in this work for the fiscal year 1925 and a like estimate for the year 1926. At the last conference of state health officers, a resolution was unanimously adopted asking that steps be taken to create a registration area for morbidity reports comparable to the registration areas of the census bureau for births and deaths.

Automobile Fatalities.—The Department of Commerce announces that reports from thirty-nine cities of 100,000 population or more show more automobile fatalities in the four weeks ending September 12 than in the previous four weeks. In fifty-seven cities aggregating a population of 27,000,000 there were 3,313 automobile fatalities reported from January 1 to September 12, and of these 13 per cent. were reported in the last four week period. Norfolk reported no fatalities for the last eight weeks, and Albany, Cambridge, Dallas, El Paso, Fall River, Fort Worth and Somerville none for the last four weeks. Somerville, with four deaths, holds the record thus far for 1925. New York has reported to the Department of Commerce 638 automobile fatalities; Chicago, 410; Philadelphia, 191; Detroit, 183, and Cleveland and Los Angeles, 154.

Library Association Protests High Cost of German Publications.—The executive committee of the American Medical Library Association is making an investigation of the present high cost of German medical publications. It is hoped to determine whether or not concerted action on the part of medical libraries of America will cause German publishers to curtail their output and to reduce the cost of their publications to American purchasers. It is pointed out that many American libraries and publishers have donated subscriptions to German libraries and physicians, but that German publishers have seemed to appreciate but little this evidence of good will. In order to obtain evidence of the interest in some joint action in the matter, those willing to aid in the movement are asked to communicate with Miss Margaret Brinton, librarian, Mayo Clinic, Rochester, Minn.

New England Surgical Society.—The annual meeting of this society will be at Springfield, Mass., October 2-3, at the Hotel Kimball, under the presidency of Dr. John W. Keefe, Providence, R. I. There will be clinics at the Springfield Hospital Friday and at the Mercy Hospital Saturday. Among the speakers will be Dr. Charles L. Scudder, Boston; Dr. Ernest L. Hunt, Worcester, Mass.; Dr. Daniel C. Patterson, Bridgeport, Conn.; Dr. Horace P. Stevens, Cambridge; Phileman E. Truesdale, Fall River; Dr. George A. Moore, Brookton, Mass.; Dr. Carl M. Robinson, Portland, Maine; Dr. Dudley Carleton, Springfield, Mass.; Dr. Walter C. Seelye, Worcester, Mass.; Dr. William F. Verdi, New Haven, Conn., and Dr. Alfred M. Rowley, Hartford, Conn. The annual dinner will be at the Longmeadow Country Club, 7:30 p. m., Friday. The ladies are invited to a tea at the Springfield Country Club, at 4 p. m., Friday.

Bequests and Donations.—The following bequests and donations have been announced recently:

St. Joseph's Mercy Hospital, Webster City, Ia., $30,000, by the will of the late C. J. Pitcher.

Mrs. Anna Cook, Collinsville, Ill., has donated a site for a hospital for that city, provided construction is started previous to her death.

The New York Skin and Cancer Hospital, New York City; St. Christopher's Hospital for Babies, Brooklyn; the Brooklyn and Jewish Hospitals, Brooklyn, and the Graham Home for Old Ladies, Brooklyn, each $5,000 by the will of the late William D. Hoxie.

The Pennsylvania Hospital, Philadelphia, $40,000; the Philadelphia Orthopedic Hospital, $8,000; the Visiting Nurse Society, $3,000; The Pennsylvania Hospital, Philadelphia, for the use of the social service department, $2,000; the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases, $1,000; the Babies' Hospital and the Oncologic Hospital for Cancer, each $500; by the will of the late Mary F. Small.

The Presbyterian Hospital, New York, sufficient funds to endow a bed in memory of her parents and to endow a room, by the will of the late Mrs. Anna A. Johnston.

St. Joseph's Hospital, Yonkers, N. Y., $200 by the will of the late Agnes L. O'Rourke of Yonkers.

Mount Sinai Hospital, New York, $100,000 by the will of the late Mrs. Emma Rosenwald.

The Montefiore Hospital, New York, $30,000, and Mount Sinai Hospital, New York, $10,000, by the will of the late Mrs. Ida R. Cullman.

Graham Hospital, Canton, Ill., $50,000 by the will of Joseph Murphy.

St. Vincent's, St. John's, St. Alexis, and St. Ann's hospitals, all of Cleveland, $200 each in the will of the late Francis J. Frawley.

American Roentgen Ray Society Election.—About 450 physicians attended the twenty-sixth annual convention of the American Roentgen Ray Society, at Washington, D. C., September 22-25. Following installation of the president, Dr. Thomas A. Groover, Washington (who is also president of the Medical Society of the District of Columbia), by Dr. George W. Holmes, Boston, the retiring president, there was a symposium on gallbladder disease. A dental clinic was held by Arthur B. Crane, D.D.S., Washington, and L. M. Christie, D.D.S., Washington, to demonstrate the need for closer cooperation between the medical and dental professions. The Caldwell lecture, an annual feature, in memory of Eugene Caldwell, New York, a martyr to the roentgen ray, was delivered by Dr. James Ewing, professor of pathology at Cornell University Medical College, New York, who spoke on "Tissue Reactions to Radiation." The election of officers for 1926 on the last day of the convention made Dr. Russel D. Carman, Mayo Clinic, Rochester, Minn., president-elect; Drs. Patrick F. Butler, Boston, and Charles M. Richards, San Jose, Calif., vice presidents; Dr. Charles L. Martin, Dallas, Texas, secretary; Dr. William A. Evans, Detroit, treasurer, and Dr. William M. Doughty, Cincinnati, member of the executive committee. The next annual meeting will be held in the spring of 1926 at Detroit, Mich.

FOREIGN

Conference on Congenital Syphilis.—The French League Against the Venereal Peril has organized a conference for the first week in October at Paris to discuss congenital syphilis, its preventive treatment and the treatment of infants and children with manifestations of congenital syphilis.

University Chair of Physical Culture.—Our exchanges state that H. Altrock, a leader in the movement for physical training and athletics in Germany, has been called to the newly founded chair of Pädagogik der Leibesübungen at Leipzig, the first professorship of physical culture in the country.

Reception to Visiting Spanish Physicians.—The medical societies of Berlin, Germany, united in a reception to the thirty-six Spanish physicians now touring Germany. Professor Ferrán, a member of the party, announced that he would donate material to those who would like to study the results of his research on the mutation of tubercle bacilli and vaccination against tuberculosis.

Centennial of Medical School.—In the second week of November will be celebrated the centenary of the Regia Escola de Cirurgia at Lisbon. A souvenir volume is to be published with the history of the school, and the bust of the late Prof. M. Bombarda will be unveiled, and a memorial tablet to the physicians who died in clinical service. A souvenir medal is also planned and a retrospective exposition, and series of postgraduate lectures throughout the month. The students are also organizing athletic events. Profs. Ricardo Jorge, Bello Moraes and Egas Moniz are to deliver the main addresses.

Personal.—The Minich prize, awarded by the Venice Academy of Sciences, has been divided between Prof. L. Castaldi, Florence, and Prof. P. Enriques, Padua, for their works, "Influence of the Suprarenal Cortex on the Growth of the Skeleton" and "Functional Relations Between the Endocrine Glands and Fracture of Bones." The topic appointed for competition was "Influence of the Endocrine System on the Skeleton."——Dr. Vogel-Eysern, Davos, is the secretary of the newly organized International Bioclimatic Federation.——The Graefe prize awarded by the German Ophthalmologic Society was not given entirely to Prof. E. Seidel, Heidelberg, as announced at first, but was divided equally between him and Prof. von Szily, Münster. The prize winning research of the former was on the interchange of fluids in the eye, and glaucoma; of the other, on embryology and teratology of the eye.——Dr. Pio Naldi, who was condemned to seventeen years' imprisonment for the killing of Count Bonmartini, has had part of his term condoned and has been rehabilitated by the Turin court of appeals. He has settled at Benevento.

Government Services

U. S. Public Health Service

Surg. Charles Armstrong has been directed to proceed to such places as may be necessary up to September 30, and return, to investigate complications associated with vaccinations against smallpox.——Acting Asst. Surg. Albert S. Gray has been directed to proceed from time in time up to September 30 on receipt of written instructions, to Barre, Vt., and return, in connection with the physical examinations made in the marble quarries at Barre.——P. A. Surg. Claude W. Mitchell has been directed to proceed to Baltimore, and return, for a conference relative to studies of diphtheria conducted in that city.——Surg. Gleason C. Lake was directed to proceed, August 1, to Norton, Va., and such other places as necessary to investigate an outbreak of tularemia.——Senior Surg. Taliaferro Clark was directed to proceed about July 31 to Hagerstown, Md., to inspect the progress of child hygiene studies being conducted at that place.——Dr. John F. G. Gates has been appointed assistant surgeon in the regular corps of the U. S. Public Health Service.——Acting Asst. Surg. William W. Hoyt has been relieved from duty at Marseilles, France, and assigned to duty at Glasgow, Scotland.——Surg. J. G. Townsend has been directed to proceed from Washington, D. C., to Baltimore and return, in connection with influenza investigations.——Asst. Surg. Kenneth F. Maxcy has been directed to proceed from Montgomery, Ala., to Savannah, Ga., and return, in connection with studies of Brill's disease.——Surg. James P. Leake has been directed to proceed from Washington, D. C., to Cincinnati and other points in that vicinity, and return, in connection with tetra-ethyl lead gasoline studies.——P. A. Surg. J. F. Mahoney has been relieved from duty at Ellis Island, New York, and assigned to duty at Dublin, Ireland, and will be detailed temporarily to Cobh and Belfast to meet emergencies in the examination of aliens.——Acting Asst. Surg. Neil E. Taylor has been directed to proceed from Cincinnati to Hartford, Conn., and other places in that vicinity as may be necessary, and return, in connection with goiter study.

Army Personals

Capt. Virgil A. Harl, M. C., U. S. Army, has resigned, effective October 30.——Major James A. Bethea, Washington, D. C., will sail about Jan. 6, 1926, from New York to the Philippine Islands for duty.

Three Hundred Changes in Veterans' Bureau

Efforts are being made by the director of the Veterans' Bureau to place the medical personnel of the bureau on a more stable basis. Director Hines recently conferred with President Coolidge to obtain approval of a plan to create a medical corps in the bureau similar to that of the army and the navy. General Hines explained that the efficiency of the medical officers would be advanced. He said that at present there are more than 1,700 medical officers in the Veterans' Bureau, and that there were more than 300 changes in the personnel in the last year, which in itself is proof that action should be taken to place Veterans' Bureau physicians on a more stable footing. General Hines told the President that the proposed medical corps would not add more than $100,000 to the annual expense of the Veterans' Bureau.

Special Instruction for Navy Officers

The Bureau of Medicine and Surgery, Navy Department, announces that it is ready to receive applications from officers who wish to specialize. The next course in aviation medicine at the Army School, Mitchell Field, Long Island, N. Y., will begin in January, 1926; those who desire to qualify as flight surgeons should make application before December 1. The bureau desires to call the attention of medical officers to the need and importance of laboratory work, and applications for special instruction in this field are assured of receiving favorable consideration. A number of medical officers, fully qualified, who desire fellowships in surgery, should submit their applications not later than July 1, 1926.

Sept. 12, 1925.

Protest by Irish Physicians Against the Government Proposal to Establish a Seperate Medical Register

The proposal to establish in Ireland a medical register separate from that of Great Britain has produced an intense controversy in which the government of the Irish Free State is on one side and practically the whole Irish profession, including the ordinary nationalist supporters of the government, are on the other. It is a question of nationalism—always a powerful force in Ireland—versus the interests of the medical profession. A meeting of several hundred physicians from all parts of the Free State was held in the Royal College of Surgeons, Dublin, to protest against the proposal of the Free State government to establish a separate register. Mr. R. C. B. Maunsell, President of the Royal College of Surgeons, Ireland, who presided, said that the agitation had not been undertaken in the interests of physicians now practicing, as the proposed change would not affect their well-being, but was solely in the interests of future generations of physicians, and through them of the public. Leaders of the profession had no political motive, nor did they wish to embarrass the government; but when the executive council had declared its intention to advise a change which would almost certainly bring ruin on the Irish School of Medicine and Surgery, it was incumbent on those whose duty it was to guard and cherish that school to point out the disastrous consequences of proposed legislation. The Dublin surgeon Sir Arthur Chance said he had the opinion of an authority, which he unhesitatingly bowed to, that on the expiration of the present arrangement in February, 1926, two things would follow automatically. First, the Irish branch of the medical council would consist wholly of Ulster members and control would be transferred to Belfast; second, the medical act of 1886, with all sections relating to colonial and foreign lists and reciprocal recognition of colonial diplomas and physicians, would cease to apply to the Free State. The machinery for reciprocity would be destroyed by the Free State's own action. The only way of restoring power to the Free State to apply for real reciprocity would be for the South Irish and the British parliaments to pass acts, simultaneously. If a separate register was set up in the Free State, the medical council would be like a bull with a ring in its nose and would have to go when and where the rope led it. The impotence of the Free State medical council would not enhance the dignity of the Free State, while there was not a colony or dominion today in the British empire which would not leap at the advantages the Free State government proposed to forego. A second resolution was passed, that, should the conference not come to a satisfactory conclusion, a public meeting be held at an early date to enable the governors and subscribers of hospitals to discuss the effect of the proposed change. Surg. John S. M'Ardle said that Irish hospitals would lose the services of a large number of students who now gave services freely to those institutions. Sir Thomas Myles said that the public hardly realized how much the efficiency of Dublin hospitals depended on the services rendered freely by the students. On the other hand Mr. Cosgrave, president of the Free State executive council, has made a momentous statement to a deputation of the president and fellows of the Royal College of Physicians of Ireland. He said that a final and definite decision had been made to promote a bill in parliament for the establishment of a medical council and register for the Free State. He hoped that the Irish physicians would cooperate with the government in the framing of the necessary legislation. When the bill had been passed, his government would approach the British government with a view to obtaining some form of reciprocity between the countries. He believed that he would obtain such a measure of reciprocity as would safeguard the status of those seeking Irish medical qualifications. The deputation urged that, in the meantime, the existing conditions be allowed to continue. Mr. Cosgrave was sympathetic with this request, but insisted that any such conditions must not be used to delay the settlement of the Irish register. He said that if the medical profession was willing to cooperate with him he would be willing to meet them, but if they should refuse cooperation the government was prepared to go to the country and fight the matter out on the hustings.

Fear by Irish Veterinary Surgeons of a Separate Register

The proposal for the institution of a separate medical register for the Free State, it is feared, will be followed by a similar proposal in respect to veterinary surgeons, who at present form part of the corporate body of the Royal College of Veterinary Surgeons, with headquarters in London. The divorcement from this body and the investment of sole control within the borders of so small a country as the Free State may prove disastrous to the Veterinary College of Ireland, located in Dublin, as it will contract the field for appointments which graduates of the college, the only one in Ireland, have hitherto enjoyed. Since the opening of the college in 1900, up to the end of 1924 there have been 411 graduates, of whom 212, or 51.58 per cent., are practicing in the Irish Free State. The remainder (48.42 per cent.) are either located in northern Ireland (14.35 per cent.) or outside Ireland (33.1 per cent.) in British government service of the army or colonies, or practicing in Great Britain. The fear of separation appears already to have caused a diminution of entrants, for only five students presented themselves for examination at the end of the first year's professional course in July last.

Two Types of Tsetse Fly

In a letter to the *Times*, Dr. G. D. Hale Carpenter, senior medical officer in charge of trypanosomiasis, Uganda, calls attention to confusion arising from looseness of expression in discussions of the tsetse fly problem. He points out that there are two tsetse flies: (*a*) those inhabiting bush of greater or less density not necessarily near water, and (*b*) those requiring thicker forest and proximity to water. The first-named group contains *Glossina morsitans*, *G. pallidipes*, and the recently discovered *G. swynnertoni*. The former species was known as "the fly" to the South African pioneers, and pallidipes was the first species proved by Sir David Bruce to be the carrier of "fly disease" of cattle; together with *Glossina morsitans* it is the most fruitful cause of this. Subsequently, however, the allied human disease, trypanosomiasis, devastated Uganda, and when it was proved to be carried by *Glossina palpalis*, which typically inhabits thick forest near the water, attention was naturally directed rather toward the species directly inimical to man than to those only indirectly harming him through his cattle. After the subsidence of the great epidemic in Uganda, attention was again directed to *Glossina morsitans* on account of an acute human disease carried by it and not causing the symptoms typical of trypanosomiasis. More recently, *Glossina swynnertoni* has been shown to carry this disease. Thus, at the end of the nineteenth century the term "the tsetse" would have been generally interpreted to mean *Glossina morsitans;* but when the great epidemic was raging in Uganda at the beginning of this century, the term would probably have connoted in the public mind the water-frequenting *Glossina palpalis*. But the pendulum has now swung back again to accentuate the importance of the *Glossina morsitans* group, partly on account of the great attention paid to it by the recent parliamentary commission to East Africa. Extermination of the tsetse fly is at present much discussed, but it is necessary to specify which tsetse fly. The species of the first group can be attacked by systematic burning of the bush on a large scale in the dry season. How can this be done so as to affect *Glossina palpalis* living near the water, where the vegetation is always green and usually of very dense type? Sufficient clearing to destroy the fly is quite beyond the powers of the limited population inhabiting infested areas, and the utmost that seems possible from purely administrative measures is the concentration of the population within areas of size no larger than can be made safe by the united efforts of the inhabitants.

Increase of Railway Accidents

More people were killed and injured in accidents to trains, rolling stock and permanent way on British railways during 1924 than in any year since 1920. According to the ministry of transport, returns of accidents and casualties on the railways of Great Britain for the year ended Dec. 31, 1924, 42 persons were killed in 1924 and 683 injured, as compared with 19 and 566 in 1923, 21 and 519 in 1922, and 30 and 678 in 1921. In accidents caused by the movement of railway vehicles, exclusive of accidents to the trains themselves, 366 people were killed and 6,538 injured, 2,677 of the latter number being passengers and 3,764 employees of the company. In accidents on railway premises not connected with the movement of railway vehicles, 54 people were killed and 18,420 injured. The totals for the year under review show that 462 people were killed and 25,641 injured, as compared with the following number for the previous four years: 1923, 407 and 23,104; 1922, 402 and 19,344; 1921, 416 and 18,873; and 1920, 635 and 25,143. There were 290 train collisions in 1924, 408 derailments, 331 cases of trains running into level crossing gates, 98 fires, and 24 miscellaneous accidents to trains. Of accidents to, or failure of, rolling stock, the most frequent were failures of coupling apparatus, to the number of 10,586. Sixty-two cases of derailment of passenger trains occurred, and in 140 cases trains ran into animals on the line.

French and English Birth Rates

It is a current misconception that the stationary population of France (a diminishing one but for immigration) is due to the low birth rate. But the French birth rate approximates closely the English one, although in England there is a steady increase of population. The explanation is that what is wrong with France is the infant mortality. The French birth rate for 1923 was 19.4 per thousand of population, while that of England and Wales was 19.7. The rate for the latter in the first quarter of 1925 was equivalent only to an annual rate of 19.4. On the other hand, the death rate of France in 1923 was 17 per thousand, as compared with 11.6 in England and Wales. Deaths of infants under 1 year of age in the same period were 96 per thousand births, as compared with 69 in England and Wales.

Air Pollution in the City of London

Dr. Howarth, health officer for the city of London, refers to the evil from coal smoke. During July, 1924, the amount of deposit registered as falling in the city was 53 tons. Of that mass, 24.9 tons was soluble and 28.7 tons insoluble, and consisting of tar, carbon, and grit. For many years it has been increasingly obvious that the use of electricity and gas for heating and cooking is contributing to the diminution of the nuisance from smoke. The cost of electricity is still far too great for its general use, but the substitution of gas for coal and coke in restaurants and business premises is practicable.

Diphtheria in London

Reference to the increasing prevalence of diphtheria in London is made in the annual report for the year 1924-1925 of the Metropolitan Asylums Board. There is a popular tendency, it says, to class diphtheria with scarlet fever, typhoid and certain other infectious diseases, as one that modern medical science has definitely controlled. That, however, is far from being the case, and London especially should look for an advance comparable with the introduction of the antitoxin treatment thirty years ago. The board's figures show that the attack on diphtheria has fallen behind that directed against the other infectious diseases. This disease, which is now the most destructive of the infectious diseases encountered in Great Britain, and, at any rate in London, appears to be resisting attack. It is suggested that education authorities should follow the lead of New York and undertake the testing and immunization by the Schick method of all children of school age.

Clinical Types of Pulmonary Gangrene

At the recent congress of medicine in Nancy, Drs. Bezançon and De Jong presented an excellent paper on clinical types of pulmonary gangrene. They emphasized that the term "pulmonary gangrene" had become more comprehensive recently. At present the conception includes all fetid suppurations of the lung. Most commonly they are complications of bronchial dilatation; less frequently they are caused by septic pulmonary embolism, air-borne infection or tracheal deglutition of food or pus. Primary types follow general weakening or are without assignable cause. The authors distinguish three principal types: 1. An acute type (the embolic type); with genuine septicemia; signs of localization lacking or not discoverable till late. In this Rist emphasized the diagnostic significance of thoracic pain. 2. An acute type with signs of localization; genuine pneumonia, rapid spreading and cavitation. Here the onset may be sudden and the evolution rapid; in other cases the gravity of the symptoms coincides with the appearance of cavities. 3. Localized types with successive periodic attacks, which are the forms on which Bezançon and De Jong dwelt, calling attention to the polymorphism of this type and pointing out that the onset—which may take on the form of hemoptysis—may be sudden or insidious. They hold that roentgenologic signs, which are exceedingly variable, changing from day to day, cannot be relied on to differentiate these types. The same thing is true of physical signs. The successive periodic attacks are, however, of great significance in recognizing this type of pulmonary gangrene. The attacks are distributed over several years (usually three or four). They are followed by remissions during which there is a chance of recovery. Sometimes the sputum ceases to be fetid, but, as a rule, expectoration persists. Relapses generally occur and the patient gradually grows weaker. The end is often hastened by grave pleural complications, which are more frequent when the gangrenous focus is superficial. Occasionally a pain in the side and intense dyspnea point to the opening in the pleura of the gangrenous focus.

The authors considered that the bronchial type did not merit a description. They pointed out that purulent bronchitis is not associated with gangrene and that it is caused only by a collection of anaerobic organisms which are responsible for its particular character. The association of tuberculosis and pulmonary gangrene is exceptional. Usually it is only a slight gangrene of the walls of a large cavity or a bronchus. The diagnosis of pulmonary gangrene is difficult, for all the pulmonary cavities opening into bronchi easily become the seat of fetid suppuration. The same is true of pulmonary abscess, interlobar pleurisy and dilatations of the bronchi. The chronicity of certain pulmonary gangrenes with periodic flare-ups add to the difficulties of the clinician. Hemoptysis is a significant sign if it occurs repeatedly. If laboratory examination of the sputum reveals numerous polymorphous micro-organisms, spirochetes or fusospirillary forms, that will aid in the diagnosis. Bezançon and De Jong stressed the importance of the labors of Veillon, Zuber and Rist, who established the part played by anaerobes in gangrenous processes. In dealing with the importance of spiral organisms in pulmonary gangrene, they spoke of the association of fusospirillary forms and of the spirochete occurring in Castellani's hemorrhagic bronchitis (bronchospirochetosis).

In discussion, M. Rist gave his point of view, emphasizing the types of gangrene that develop after aseptic surgical operations, gastrostomy, gastro-enterostomy and the radical treatment of epigastric hernia. He recommended artificial pneumothorax as early treatment possibly combined with serotherapy and arsenotherapy. M. Jaquerod supported the opinion of the authors that pulmonary tuberculosis and pulmonary gangrene were but rarely associated.

Regulations for the Protection of Mothers and Infants

Signor Federzoni, minister of the interior, has appointed a commission to draw up a preliminary set of regulations for the protection and assistance of mothers and infants. The commission consists of Professor Marchiafava, chairman; Prof. Ernesto Pestalozza, Dr. Alberto Pironti, Signor Martire and Professor Valagussa.

The Fourteenth Italian Congress of Stomatology

The fourteenth Italian Stomatologic Congress, which is under the auspices of the Federazione stomatologica italiana, will be held at Fiume, September 10. This congress is important from both the scientific and the professional standpoint. Many Italian and foreign stomatologists have sent communications on various subjects. Hungarian stomatologists, chiefly, will attend. After the congress at Fiume, the Italians will inspect the Stomatologic Institute in Budapest and will be present at the unveiling of a monument in memory of the Hungarian stomatologist von Arkövy, who died recently.

The Italian-English Reciprocity Agreement as to Licensure in Medicine and Surgery

The new reciprocity agreement between Italy and Great Britain allows graduate physicians and surgeons of either nation to have their names enrolled in the medical register of the other, whereby they may practice their profession in either country without having to pass a new examination.

Prize Open to Italian Medical Officers

In connection with the ceremonies that the Italian medical corps held last year in memory of the physicians who fell during the war, Surgeon General Ferrero di Cavallerleone established a fund of 20,000 liras, stipulating that the quadrennial proceeds should be awarded to the medical officer in active service who, during the four years, had won the greatest distinction, either through the publication of an important work or treatise of a medicoscientific character or through having made some important scientific discovery. In case no such award can be made, the proceeds shall be given to the medical officer on active duty who, by virtue of his character and attainments, gives the best assurance of being able to profit by a period of study abroad in the military medical service of some other nation. By a recent royal decree, the foundation has been approved.

Typhoid and Antityphoid Vaccination in the Italian Army

In connection with an outbreak of typhoid fever that occurred in a regiment of field artillery during last year's shooting tournament, Colonel Memmo, M.D., of the ministry of war, completed studies on the epidemiology of typhoid in the Italian army. Antityphoid vaccination was first introduced into the army during the war with Libya (1912-1913) and was made compulsory in March, 1917. The aqueous vaccine prepared by either the Wright-Leishmann, the Pfeiffer-Kolle or the Vincent (ether) method was first used. With these vaccines three successive injections, at intervals of one week, were necessary. This proved inconvenient for several reasons: the immobilization of troops for a certain number of days on three separate occasions; the difficulty of getting all the men to submit to all three vaccinations, and the necessity of enduring the reaction phenomena three times. The lipovaccine proposed by Le Mignic was therefore adopted in a ministerial circular of February, 1920. By this method, only one injection is given the troops, and this soon after they enter the service, or about thirty days after the vaccination against smallpox. The adjoined table shows incidence of typhoid per thousand effectives during the last twenty-five years:

1899	5.4	1908	3.2	1917	2.6
1900	6.2	1909	1.3	1918	1.3
1901	5.2	1910	1.9	1919	0.2
1902	4.1	1911	4.0	1920	0.5
1903	4.1	1912	7.1	1921	2.8
1904	4.4	1913	7.1	1922	2.7
1905	5.1	1914	8.5	1923	2.5
1906	4.4	1915	17.9	1924	4.0
1907	3.1	1916	1.2		

These figures give rise to certain epidemiologic considerations. The war with Libya and the World War (particularly during 1914 and 1915) lowered organic resistance of the soldiers, and added to sources of infection and contagion. However, the results of antityphoid vaccination during the war with Libya were good, for the morbidity among the nonvaccinated troops was 35.3 per thousand and that of the vaccinated was 7.2 per thousand (Ferrero di Cavallerleone). Also during the recent war, vaccination and revaccination lowered the morbidity rate from 17.9 to 1.3 per thousand. These results may be attributable not solely to vaccination but in part to the hygienic measures that were instituted.

But the foregoing morbidity table reveals that during the last four years the proportion of men contracting typhoid (1921, 2.8 per thousand; 1922, 2.7; 1923, 2.5, and 1924, 4.0) has increased. Since there has been no slackening in the campaign against typhoid in the army, it is difficult to explain this increase. Professor Memmo, however, has observed a sort of decennial rhythm in the incidence of the disease during the last quarter century. The disease abated from 1900 to 1909 (from 6.2 to 1.3 per thousand), increased during the following decade, aggravated by the exigencies of war, and again abated to a morbidity rate of 0.2 per thousand in 1919. Since 1919 there has been a slow upward trend. The causes for this rhythmic movement (which may be noted in almost all infectious diseases) may be sought in several circumstances: immunity, predisposition of the organism, conditions of time and place, pathogenic action of the micro-organisms, and vehicles of the epidemic.

Cursory examination of the morbidity statistics seems to indicate that antityphoid vaccination has not exerted any beneficent influence on this periodicity. But it will be seen that the minimum has been reached only since the introduction of antityphoid vaccination, while the maximum was the direct result of the World War.

We have not as yet exact data for comparison of morbidity among the vaccinated and nonvaccinated. The statistics of 1921 reveal that in that year there were 335 cases of typhoid among the vaccinated troops and 316 cases among the nonvaccinated. Since the number of men not vaccinated, though it does not represent the total number under arms, is certainly much greater than the number of vaccinated, among the vaccinated the morbidity should have been less and higher among the nonvaccinated, assuming that the number exposed to typhoid was approximately the same in the two classes.

BERLIN

Sept. 12, 1925.

Gratuitous Treatment of Colleagues

Since time immemorial German physicians have accorded gratuitous treatment to colleagues and their families. What was at first a usage has come to be regarded in many quarters as a duty, with the result that many societies have designated it as such in their by-laws. Under present economic conditions, it seems inadvisable to continue the custom. In several articles that appeared in the *Deutsche medizinische Wochenschrift,* nearly twenty years ago, Professor Schwalbe, the editor, indicated some disadvantages arising out of the custom and asserted that gratuitous treatment of colleagues should not be regarded as an unquestionable right. The disadvantages affect both the physicians and their patients. Now that the number of specialists has so increased, and they are so often called to advise general practitioners, though the opposite is seldom true, we can scarcely speak of exchange of services. Numbers of physicians accept treatment of specialists or consult authorities. With some specialists these colleagues constitute a considerable portion of their patients, so that gratuitous treatment of colleagues deprives the specialists of appreciable portions of their incomes. Gifts of wine, foodstuffs and other articles by no means make up the loss of cash fees. On the other hand, it must be painful for a practitioner or his family to accept the services of a colleague without an opportunity to pay him. In view of present economic conditions, it is pardonable that specialists and consultants, when colleagues unknown to them seek their services, do not find time for them so readily as for paying patients. For these reasons, physicians often prefer not to mention their profession when in need of treatment.

Recently Dr. Schwalbe in the *Wochenschrift* reopened the question in connection with a case which has proved the unsoundness of the principle of gratuitous treatment of colleagues. An ophthalmologist treated a physician in Rhenish Prussia for grave iritis. The specialist claimed that he had visited his colleague's residence at least twenty times and that the patient had come to his office at least 300 times. When he demanded 1,700 marks for professional services, the patient refused. In court, the plaintiff asserted that not only was the alleged number of visits and consultations erroneous and the amount demanded unjust, but also that it was the custom for physicians to treat one another gratuitously. The court asked the *Aerztekammer* (chamber of physicians) of the district whether this was customary among physicians, and also whether specialists usually treat colleagues without charge even though the case is protracted. The *Aerztekammer* answered in the affirmative, whereupon the court rejected the petition of the ophthalmologist, citing as authority the *Bürgerliche Gesetzbuch* (civil code of laws). Schwalbe demands that *Der deutsche Aerztetag* or at least the Prussian *Aerztekammernausschuss* announce that gratuitous treatment by colleagues no longer be regarded as a professional custom or duty, not only in the interests of the attending physicians but also for the benefit of the colleagues or their families in need of treatment. He refers to an utterance of *Oberreichsanwalt* Ebermayer, a collaborator of the *Wochenschrift* on subjects of jurisprudence, who advises that physicians cease to accord one another gratuitous treatment, because it is not in keeping with the present changed conditions. It should be left to the attending physician to decide, in each case, whether or not he shall require a fee.

Regulations Governing the Sale of Canned Milk

In recent years, there have been repeated alleged grievances in connection with the sale of canned milk. Analysis revealed a fat content ranging between 6.4 and 8.1 per cent. Four samples, after they had been diluted in accordance with the printed directions, yielded solutions of which the content in dry milk substance was much less than that of ordinary milk. Five samples of condensed milk of various origin yielded fat content between 7 and 14 per cent. Differences in price of the various brands corresponded in a general way to variations in fat content. The dilution recommended in printed directions on a can of condensed milk is, as a rule, the only indication to the purchaser as to the degree of evaporation of the product and is therefore a criterion of its value. The buyer expects that if he dilutes the canned product according to directions he will secure an equivalent of ordinary milk.

Samples of canned milk were purchased in different stores and it was observed that some foreign products with foreign labels were merely plain sterilized milk and in other cases condensed partially skimmed milk. Both, however, were sold under the name "condensed milk." One shop advertised condensed partially skimmed milk as "condensed milk" and sold condensed whole milk as "cream." Another shop designated condensed whole milk as "Libby's cream."

These deceptions can be combated from various angles: through the law pertaining to the sale of foodstuffs, on the basis of the penal code (*Strafgesetzbuch*), the law against unfair competition, and, in most cases, on the basis of misleading statements made on the containers of foodstuffs (act of June 26, 1916). A new draft of the law pertaining to the sale of provisions is being prepared, and it is thought that this will deal with the sale of canned milk.

Marriages

Richard Reinoehl Gates, Lebanon, Pa., to Miss Anna S. Groth of West Philadelphia, August 20.

Leo Edward Stenger, Logan, Ohio, to Miss Hazel Jeanette Smith of West Jefferson, September 8.

Clarence Lu Verne Smith of Iowa City to Miss Marion MacKenzie of Muscatine, Iowa, July 11.

Milton B. Galloway to Miss Ethelle Eugenia Richards, both of Webster City, Iowa, August 6.

John F. Veltman, Holland, Mich., to Miss Esther L. Jongewaard of Ames, Iowa, recently.

Richard Martin Rutledge, Peoria, Ill., to Miss Dorothy Phillips of Delavan, September 19.

Daniel Greenlee Caldwell, Brooklyn, to Miss Ivey Tille Bets of Chester, Pa., June 6.

Harold Leon Goldburgh to Miss Hortense Pearlman, both of Philadelphia, August 2.

Maxwell H. Thurm to Miss Dorothy Raphael, both of Brooklyn, September 6.

Richard M. Brickner to Miss Ruth Helen Pilpel, both of Brooklyn, July 1.

Deaths

Eugene Robert Kelley ⊕ Commissioner of Public Health of Massachusetts, committed suicide at his home in Boston, September 27, aged 42. Dr. Kelley graduated from Johns Hopkins University Medical Department, Baltimore, in 1906; from 1909 to 1911, he was assistant commissioner of health of the state of Washington and commissioner of health from 1911 to 1915. He was then appointed director of the division of communicable diseases of the Massachusetts State Health Department, and in 1918 was appointed commissioner. Dr. Kelley was secretary of the Conference of State and Provincial Health Authorities of North America, from 1916-1919; president of the conference, 1921-1922, and president of the Massachusetts Conference on Social Work, 1923-1924.

John Wheelock Elliot, Boston; Medical School of Harvard University, Boston, 1878; member of the Massachusetts Medical Society and the American Surgical Association; clinical instructor of gynecology, 1888-1889, and lecturer on surgery, 1900-1905, at his alma mater; formerly on the staff of the Free Hospital for Women, Brookline, and the Massachusetts General Hospital; aged 72; died, September 17, at his home in Needham, Mass.

Earl Warren Presley ⊕ Staten Island, N. Y.; University and Bellevue Hospital Medical College, New York, 1912; president and formerly secretary of the Richmond County Medical Society; served in the M. C., U. S. Army, during the World War; on the staffs of the Richmond Memorial, Seaside and Seaview hospitals; aged 36; died, September 15, at the Staten Island Hospital, following an operation for stricture of the intestine.

Thomas McC. Lippitt ⊕ Lieutenant (j. g.), U. S. Navy, retired, Berryville, Va.; University College of Medicine, Richmond, 1897; entered the navy as an assistant surgeon, July, 1898, and was retired from active service September 25, 1902, as a result of injuries received during the Boxer rebellion in China in 1900; aged 52; died suddenly, September 16, of heart disease.

Thomas Jefferson Stout ⊕ Brinkley, Ark.; University of Nashville (Tenn.) Medical Department, 1901; past president and secretary of the Monroe County Medical Society; proprietor of a hospital bearing his name; at one time secretary of the Arkansas State Board of Medical Examiners; aged 52; died, August 30, of a bullet wound, presumably self-inflicted.

James M. Inge ⊕ Denton, Texas; Louisville (Ky.) Medical College, 1874; past president of the State Medical Association of Texas; formerly lecturer on regional anatomy at Baylor University College of Medicine, Dallas; aged 73; died, September 9, at a sanatorium in Dallas, of septicemia.

Milton Henry Edens ⊕ Anadarko, Okla.; University of Georgia Medical Department, Augusta, 1902; served in the M. C., U. S. Army, during the World War; aged 52; died, September 11, at the Wesley Hospital, Oklahoma City, of uremia, following an operation for appendicitis.

Frank Beresford Crowe ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1902; for many years chief resident physician to St. Joseph's Hospital, Reading; aged 48; died, September 12, at the National Stomach Hospital, following an operation.

John Brice Cressinger ⊕ Sunbury, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1896; health officer of Sunbury; formerly member of the city council; on the staff of the Mary M. Packer Hospital; aged 53; died, September 16.

Eli Butler Ives ⊕ Bridgeport, Conn.; Yale University School of Medicine, New Haven, 1903; past president and secretary of the Fairfield County Medical Society; on the staff of the Bridgeport Hospital; aged 47; died in September.

Henry M. Miles ⊕ Norton, Va.; Louisville (Ky.) Medical College, 1890; member of the state board of health; specialized in ophthalmology, otology, laryngology and rhinology; aged 57; was found dead in bed, September 8.

William La Fayette Mullin, Society Hill, Ala.; University of Alabama School of Medicine, Tuscaloosa, 1900; member of the Medical Association of the State of Alabama; aged 47; died, September 8, following an operation.

John Nelson Sprowls ⊕ Claysville, Pa.; Jefferson Medical College of Philadelphia, 1877; for thirty-three years surgeon to the Baltimore and Ohio Railway; aged 73; died, September 11, of carcinoma of the spleen.

Paolo Virdone ⊕ Brooklyn; University of Naples, Italy, 1899; formerly on the staff of the Wyckoff Heights Hospital; aged 50; was drowned at sea, September 7, when he jumped overboard en route to Italy.

Katherine J. Mackay Mackenzie, Port Coquitlam, B. C., Canada; Dalhousie University Faculty of Medicine, Halifax, Nova Scotia, 1895; aged 55; died recently, at New Westminster, of septicemia.

John Richmond Pratt, Manchester, N. Y.; Jefferson Medical College of Philadelphia, 1851; member of the Medical Society of the State of New York; aged 99; died, September 13, of senility.

John Knight Bucklyn, Jr., Mystic, Conn.; New York Homeopathic Medical College and Hospital, New York, 1887; aged 60; died, September 16, of heart disease and diabetes mellitus.

Frank Herrick Newland ⊕ Clifton Springs, N. Y.; Cleveland Homeopathic Medical College, 1902; county coroner; member of the board of education; aged 52; died suddenly, September 16.

Harold James Levis, Long Island City, N. Y.; University of Michigan Medical School, Ann Arbor, 1902; aged 47; died, September 11, at the Roosevelt Hospital, New York, of pneumonia.

The Propaganda for Reform

In This Department Appear Reports of The Journal's Bureau of Investigation, of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

ANACIN

The Birth and Development of a "Patent Medicine"

Anacin is a "patent medicine" marketed by the Heidbrink Company of Minneapolis. The Heidbrink concern is not primarily in the "patent medicine" business, but is listed as manufacturers of dental supplies; in fact, Dr. J. H. Heidbrink, its president, is a dentist. Some of the claims made for Anacin are:

> "Quickly relieves Headache, Toothache, Earache, Colds, Flu, Grippe, Neuritis, Neuralgia, Pain, Rheumatic Pains."
>
> "Doctors Recommend It. Prescribed Ten Years by Doctors and Dentists Everywhere."
>
> "Morning-After Headaches. That splitting, blinding, 'morning after' headache goes quickly after taking the safe Anacin tablets prescribed by physicians."
>
> "No bad after-effect on the heart"
>
> " . . . a *non-habit forming compound*."

More than five years ago a physician wrote, asking for information regarding the composition of Anacin. This was the first inquiry about and the first record The Journal had of the product. This was in April, 1920. In November, 1920, the Council on Pharmacy and Chemistry received a letter from the Heidbrink Company stating that the concern was considering the possibility of putting out certain medicinal preparations and desired to conform to the rules of the Council not only in the preparation and naming of the products but also in their marketing. The company requested that information be sent it that would allow it to act intelligently in the premise. The official rules of the Council were sent to the company and it was told that should further information be desired, it would be furnished. This was nearly five years ago. So far the Heidbrink Company has not submitted any product to the Council for inclusion in "New and Nonofficial Remedies."

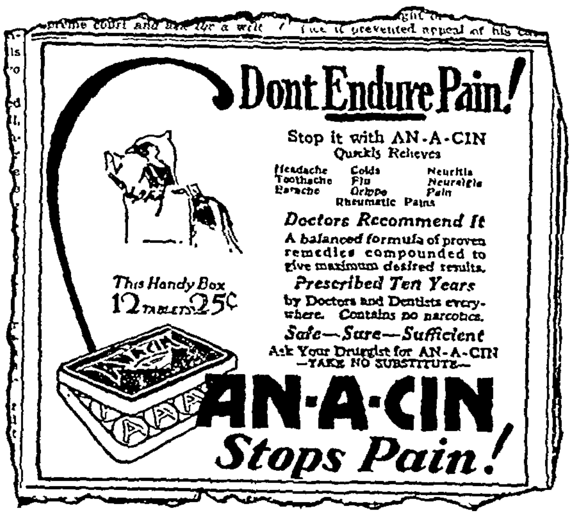
In August, 1922, Dr. F. W. Wittich of Minneapolis sent two bottles of Anacin—one bottle marked "Anacin spoiled" and the other marked "Anacin fresh"—to the American Medical Association. The doctor stated that Anacin was a tablet made by a wholesale manufacturing concern of Cleveland for the Heidbrink Company of Minneapolis, and had the following formula:

Acetphenetidin (Phenacetin)	3 grains
Acetylsalicylic acid (Aspirin)	3 grains
Quinin sulphate	⅓ grain
Citrated Caffein	⅓ grain

Dr. Wittich explained further that Anacin, which had been on the market locally for two years, had been used extensively by him whenever the salicylates were indicated. Recently a bottle that he had purchased showed deterioration and Dr. Wittich asked for a possible explanation of such spoilage. He was told that it seemed probable that the tablets had decomposed, due to the action of citric acid (in the citrated caffein) on the acetylsalicylic acid with the formation of free acetic acid. He was told further that citrated caffein had no advantage over the alkaloid except that the citric acid renders the caffein more soluble.

It was suggested to Dr. Wittich that, in the interest of rational therapy, instead of prescribing a "patent medicine" sold under a non-descriptive name, he determine whether the effect from the nostrum might not be secured from the administration of aspirin alone, and if not, that he find out which of the other constituents affected the action of the acetylsalicylic acid. No reply was received to this letter, but soon thereafter the formula of Anacin seems to have been changed and caffein alkaloid was used instead of citrated caffein.

A physician who recently wrote to the Heidbrink Company for information regarding Anacin received a letter from J. A. Heidbrink, D.D.S., declaring that "the Anacin formula was worked out by Dr. F. W. Wittich and his associates at the University of Minnesota Medical Department, where he had a professorship." Dr. Heidbrink also enclosed some mimeographed sheets giving what he described as "Dr. Wittich's statement concerning Anacin and its ingredients." This description mentioned that the tablet contained aspirin, acetphenetidin, quinin sulphate and caffein alkaloid but gave no information regarding the proportions of these ingredients. The same is true regarding the circular in the trade package. As under the federal law the amount of acetphenetidin has to be declared, these figures are on the small vest-pocket tin in which Anacin is sold, namely: that it contains 187 grains of acetphenetidin to the ounce. As the weight of the individual tablet is not given it necessitates a careful weighing of the tablets to determine from this the amount of acetphenetidin in each tablet. The mimeographic description ascribed to Dr. Wittich contains several statements that are without scientific foundation and also references to work that has long since been shown to be fallacious.



Dont Endure Pain!

Stop it with AN-A-CIN
Quickly Relieves
Headache Toothache Earache Colds Flu Grippe Neuritis Neuralgia Pain Rheumatic Pains

Doctors Recommend It
A balanced formula of proven remedies compounded to give maximum desired results.

Prescribed Ten Years
by Doctors and Dentists everywhere. Contains no narcotics.

—TAKE NO SUBSTITUTE—

This Handy Box
12 TABLETS 25¢

AN-A-CIN
Stops Pain!

Photographic facsimile (reduced) of a typical Anacin newspaper advertisement.

Here then we have the spectacle of a reputable member of the medical profession developing a "patent medicine" and allowing it to be put on the market for the indiscriminate sale to, and the uncritical use of, the public.

Correspondence

PHYSICAL THERAPY ABROAD

To the Editor:—Many American physicians are still in doubt as to the value of physiotherapy; on the other hand, a growing group of physicians have permitted their enthusiasm to get the better of their more sober judgment. Various electrical agents are in evidence in most of the important clinics of Europe. Galvanization is practiced both as a diagnostic and as a therapeutic agent. Hydrotherapy and heliotherapy are much in vogue at the various spas. Diathermy and ultraviolet therapy enjoy popularity both on the continent and in England, owing to the good results obtained by these agents during the war and the period of reconstruction. Ultraviolet, especially, is accepted with a greater degree of enthusiasm, owing, no doubt, to the splendid researches of such men as Hausser of Berlin, Davos of Dorno, and Hausmann of Vienna.

In England, the University of Cambridge offers a six months' course with a diploma in both radiology and physiotherapy. The didactic part is taught by Dean Scales at Cambridge, while the practical end is given at the clinics of the St. Bartholomew's and London general hospitals by Dr. Cumberbatch. The influence of Finsen is much in evidence in England because the carbon and tungsten arc lamps are the methods of choice for ultraviolet irradiation. Leonard Hill and his associates at the National Institute for Medical Research have been important factors in advancing light therapy to a more scientific basis in England, by their many original investigations in recent years.

France still has the living inspiration of d'Arsonval, the discoverer of the high frequency currents. Physiotherapy is a popular and accepted specialty, and much opportunity for study and work can be found at the Salpêtrière and Pitié hospitals. The aged d'Arsonval is a much honored man and occupies the professorial chair of medicine in the Collège de France. Paradoxically, while some of the earliest and best investigation in ultraviolet therapy was done in France by M. Henri, it is not much in evidence as a therapeutic agent.

Vienna and Berlin are in apparent agreement as to the choice and importance of the various types of the physical agents. Hydrotherapy is extensively used, and much space is devoted in the various hospitals to the many varieties of baths. Radium emanation and extract of pine baths enjoy much favor at the Kaiser-Jubiläum Hospital in Vienna and at the Rudolph Virchow Hospital in Berlin. Mud packs, called "Fango" baths, are also popular and in great evidence. Diathermy and the galvanofaradic types of currents are in constant use. The Jubiläum Hospital averages about 260 patients a day in the department of physical therapy, and monthly courses are offered to the visiting physician.

Nagelschmidt is the outstanding physician in Berlin in physiotherapy. The word "diathermy" is of his own coinage, and all that is known of the practical action of this current can be largely attributed to his investigations. He actively practices and teaches physiotherapy at his own hospital, and one hears at his clinic a babel of tongues from visiting physicians from all corners of the earth. At the Charité Hospital, Prof. C. Adams is in charge of the extensive division of physical therapy, while at the Rudolph Virchow Hospital, Laqueur is at the head of the department—by far the largest of its kind in Berlin. Courses of a month or longer are offered to visiting and graduate physicians. Berlin, however, is an expensive place at present.

Disraeli Kobak, M.D., Chicago.

IVY POISONING: ITS PREVENTIVE TREATMENT

To the Editor:—In The Journal, August 8, page 456, McNair critically reviews our report on the preventive treatment of ivy poisoning. As I directed the studies which, he says, should have been "more scientifically conducted," the duty is mine to point out wherein McNair has not quite grasped the situation.

McNair is the author of a monographic treatise on *Rhus* dermatitis which covers all its phases and includes much original work; apparently he has not perceived the difference between the scope of a monograph and a report like ours, designed to be printed in a publication such as The Journal. Our communication reported our facts to the general medical practitioner, facts of which the doctor could avail himself in his approach to the problem of human welfare. Findings of more abstruse scientific interest could be pointed out only in passing. We did not pretend to exhaust all the ramifications—indeed, it is doubtful whether The Journal could spare us space for the more extensive style of publication.

With these circumstances in mind, most of McNair's objections are disposed of at once. 1. It was quite unnecessary to use "definite quantities of the poison" in our work, as McNair would have us do. We were not interested in the percentage concentration of the virus that would induce dermatitis—the leaves and bark were tools sufficient unto us, since we were interested primarily and solely in inducing a dermatitis. Indeed, leaves and bark were preferable in our attempt to approach natural conditions as closely as possible. 2. Similarly, determination of the respiration rate, hematology, etc., were all beside the point. They were not pertinent to our phase of the subject. It would have been interminable to have essayed all the chemical and physiologic appendixes of the subject. 3. "Minimal toxic doses," as McNair recommends, would have been interesting—certainly a harmless amusement. We submit, however, that they did not require determination, because our problem was not a quantitative one. In our work only two values were concerned, one before, and the other after treatment. Hence comparative values were quite sufficient of determination. Quantitative ones were unnecessary.

There are three other criticisms that are not disposed of under our foregoing plea of "not monographic." 1. We claimed, as a new finding, that local immunity was not developed by repeated attacks of ivy poisoning. In contradiction, McNair properly calls attention to facts recorded in his monograph which clearly established priority for others *for those facts as facts.* Those facts were not interpreted by McNair, however, into the generalization that we brought out: they were part of and submerged in a running discussion of the general subject of immunity. Our intent was not to attract credit to ourselves but attention to the subject of immunity as it obtains locally. 2. McNair discusses our statement that there is probably no such thing as absolute immunity against *ivy poisoning.* In doing this he does not distinguish between (1) the artificial ivy virus and (2) ivy poisoning; i. e., between an experimental substance and the natural disease with which we are concerned. Thus, he would have us "try the poison highly concentrated and purified," etc. We were not interested in the tissue reaction against concentrated virus—only against concentrations approximate to those occurring in nature.

There are other minor criticisms which are not vital to the subject and which cannot be covered short of extensive description of the premises. As it stands, while we experience a certain sense of flattery at having drawn the lightning of Jove, we also feel some disappointment that he should not have recognized the scope of our experiments before going into print.

We still feel that our experiments and communication were of more service to the general medical public as rendered than if obscured by the multiple qualifying phases and scientific experimental appendixes such as have their very proper place in the monographic form of presentation.

Fred D. Weidman, M.D., Philadelphia.

OVA OBTAINED BY DUODENAL LAVAGE

To the Editor:—There has just come to my attention a letter written by Dr. R. S. Preston, Richmond, Va., published in The Journal, April 4, and requesting references on the subject of ova obtained by duodenal lavage. You replied that you were unable to find such a report in the literature.

While working on hookworm infected soldiers I found that the ova could occasionally be aspirated through the duodenal tube. These observations were published in the *Military Surgeon* **46**:507-513 (May) 1920. Perhaps I might also mention that the tube treatment of uncinariasis previously described in The Journal, Oct. 18, 1919, p. 1181, and in the *American Journal of the Medical Sciences* (**159**:497 [April] 1920) has continued to give superior results—in the way of *complete* parasite removal—in the hands of all those who have employed it, whether in military or in civilian practice.

John L. Kantor, M.D., New York.

AMERICAN ASSOCIATION FOR MEDICO-PHYSICAL RESEARCH—A DISCLAIMER

To the Editor:—Following is a statement relative to that portion of your article on the association mentioned which relates to me: I was not aware that my name appeared on the program of the American Association for Medico-Physical Research. If this occurred, it was wholly without my consent. I did not appear before the meeting in question. For entirely reasons personal, I cannot at this time disclose the history of my early scientific studies and graduation in medicine. Accordingly I shall discontinue the use of the title. I have not attempted to practice medicine but have devoted myself to researches in electromagnetic energies and their application to the problem of human welfare.

A. J. Pacini, Chicago.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

HOLZKNECHT ROENTGEN-RAY UNIT

To the Editor:—Recently in reading an article dealing with the therapeutic uses of the roentgen ray, I came across the term "Holzknecht" as a unit of measurement of the strength of the ray. I think it is a German term. Can you inform me as to its meaning?

E. H. Gish, M.D., Philadelphia.

Answer.—A Holzknecht unit is a unit of roentgen-ray dosage equal to one-fifth the erythema dose. A chemically prepared pastil is exposed at half the distance from the tube to the part under treatment, and the application is continued until the pastil has changed color to correspond with 1, 2, 3, 4, or possibly 5 of the color scale. This indicates that the irradiation has amounted to a corresponding number of Holzknecht units.

TOXICITY OF PYRIDIN, BENZENE, ALCOHOL —DENATURED ALCOHOL NO. 8

To the Editor:—Please give me any information on possible chances of so-called industrial poisoning from inhalations of fumes from a still containing denatured alcohol No. 8 (100 gallons of alcohol containing 1 gallon of pyridin base and 1 gallon of benzene). The case is that of a chemical worker inhaling fumes from a leaking still. Please do not publish my name.

H. E. W., M.D., Connecticut.

Answer.—In plants making denatured alcohol on a large scale, there should be such adequate protective measures that the workers are not dangerously exposed to the fumes; the closed pipe system's should be employed from the standpoint both of health and of economy (lack of waste). In large plants, therefore, one would expect acute poisoning rather than chronic poisoning, as when a break occurs in the system. In plants where the liquids are permitted to volatilize to a certain extent in the air, chronic poisoning would be expected.

The toxicology of alcohol is so well known that it needs no discussion.

Pyridin (and denatured alcohol containing pyridin) has been reported to cause an eczematous condition of the skin (Industrial Health, Kober and Hayhurst, 1924, p. 509).

Benzene (benzol) is the most toxic agent in Formula 8. Acute cases of poisoning due to benzene are of such striking character that they usually attract the attention of the physician. The chronic case, however, is often completely overlooked, especially in those plants not employing a physician, until some acute exacerbation takes place (which applies particularly to plants using open processes). Benzene is a narcotic which, when swallowed and inhaled, produces vertigo, delirium and tonic convulsions followed by deep sleep. According to Dr. Alice Hamilton, symptoms caused by inhalation in animals point to a poison with a selective action on the central nervous system, as (in order of their appearance) muscular tremors, salivation, violent twitchings, exhaustion, paralysis, narcosis, respirations first quick and then slow, rapid pulse and low temperature. "In some cases of chronic poisoning in man, petechial spots, due to small hemorrhages, have been observed. These spots have been attributed to fatty degeneration of the blood vessels. It produces leukocytosis followed by leukopenia, with an occasional increased number of erythrocytes. Larger amounts may produce an aplastic anemia. It has been stated that the aplastic anemia is due to a contamination of the drug with nitrobenzene or anilin" (New and Nonofficial Remedies, 1925, p. 66). In a study of benzene on certain aspects of metabolism, F. P. Underhill and B. R. Harris of Yale (*J. Indust. Hyg.*, March, 1923, p. 499) show that benzene exerts a catabolic influence on body tissues as a whole, as manifested by a sharp rise in the elimination of both creatin and total nitrogen. In all cases the end-results were the same; that is, all rabbits showed a leukopenia of varying degree. The New York State Industrial Commission in its *Bulletin* for November, 1920, reports two cases in men employed in an atmosphere containing benzene, who developed purpura hemorrhagica. This condition has also been reported by others. In the Second Progress Report of the Subcommittee on Benzene, National Safety Council, Oct. 3, 1924 (this and the first report may be obtained from the National Safety Council, 168 North Michigan Avenue, Chicago), the committee states that the white blood cell count is the most important early diagnostic sign of benzene poisoning. Out of a group of eighty-four workers employed in processes involving more or less continuous exposure to benzene vapors, 15 per cent. showed a white blood cell count so low as to be strikingly suggestive of chronic poisoning, indicating that besides the obvious clinical cases there exists in the industry a considerable amount of mild undetected poisoning of this type. In the opinion of this committee, the symptoms of chronic benzene poisoning (excluding the blood count) are of little value; dizziness is the most frequent symptom and pallor the most usual physical finding. The committee report also discusses a proposed method to determine the concentration of benzene in the atmosphere.

For prevention, local exhaust ventilation at the point of origin of vapors appears to be a highly efficient procedure.

CALCIUM THERAPY IN TUBERCULOSIS

To the Editor:—What value has the calcium saturation therapy of tuberculosis, if any? Please use initials only.

E. G. C., Ohio.

ANSWER.—As is stated in "Chemistry of Tuberculosis" by Wells, De Witt and Long (Williams and Wilkins Company, Baltimore, 1923), "the theory that tuberculosis is accompanied by, and perhaps dependent upon, a demineralization and especially a loss of calcium from the body, has not been supported by the best controlled investigations. There is no acceptable evidence that there is any decrease in the amount of calcium in either the blood or the tissues in tuberculosis. . . . We have no evidence that the calcium deposition in tuberculous lesions causes them to stop progressing; it is more probable that calcification *follows* the healing of human tuberculous lesions." Animal experimentation with intravenous injections of relatively large quantities of calcium chlorid solution has not been convincingly positive, and is generally negative in its result. Thus, Masini's (*Schweiz. med. Wchnschr.* **51:**223, 1921) tuberculous rabbits given 1 c.c. of 1 per cent. calcium chlorid solution intravenously twice a week lived from seventy-five to 120 days, while the controls lived from sixty-eight to 116 days.

Though a number of clinicians endorse the use of calcium compounds as giving definite clinical benefit, the enthusiastic opinion of the few has not been corroborated by the experience of the many.

ROENTGEN-RAY STERILIZATION

To the Editor:—1. In how many per cent. of the cases is roentgen-ray sterilization of men (and of women) of permanent effect? 2. Are five erythema doses of roentgen ray, given to an individual of 19 years and directed to the scrotum, able to produce sterility? (This treatment was given for erythema of the scrotum.) 3. About how many roentgenologists who were sterile as a result of the influence of the rays became fertile again? 4. Does roentgen-ray sterilization affect the libido? 5. Is there any treatment for roentgen-ray sterilization in the male?

K. B., New Jersey.

ANSWER.—1. While there are no exact statistics available, it may be stated that in most of the cases the sterilization is only temporary. The time of recuperation depends on the intensity of the treatment and on the individual constitution.

2. The treatments cited are apt to produce sterility, though the age of the patient offers a good chance for recovering the power to produce live spermatozoa.

3. This question is answered under 1.

4. Neither roentgen-ray nor operative sterilization necessarily affects the libido.

5. There is no specific treatment for roentgen-ray sterility in the male. Absolute removal from the influence of roentgen rays and general hygienic measures are essential.

THIOFLAVINE AND ACRIFLAVINE

To the Editor—The Epitome of Current Medical Literature (*British Medical Journal*, Aug. 15, 1925, p. 20) contains an abstract on "Chemical Substances Inhibiting Growth of the Tubercle Bacillus." The original paper of L. Karwacki and S. Biernacki appeared in the *Annales de l'Institut Pasteur.* They suggest that the most active substance of all—thioflavine—should be tested pharmacologically. It seems to me a very important research. How does thioflavine differ from acriflavine and other flavines, which we have been using during the last several years?

SAMUEL GINSBURG, M.D., Buffalo.

ANSWER.—Thioflavine is one of many yellow dyes that have been used in the arts for years. In 1888, two process patents for its manufacture were issued by the German Empire (to the Casella Company). The names of the various compounds ending in "flavine" are of commercial appelation and have no scientific generic basis, the "flavines" being yellow dyes. Acriflavine connotes a yellow derivative of acridin; thioflavine means a yellow substance containing sulphur. Other "flavines" have names coined in the same manner. Chemically, thioflavine is methyl dehydrothio-*p*-toluidine sulphonate. Acriflavine (the base) is diamino-methyl-acridinium chlorid. The two substances, therefore, are not closely related chemically, and from a chemical standpoint it would not be logical to predict the pharmacologic properties of thioflavine from the known actions of acriflavine.

MICHIGAN: Lansing, Oct. 13-15. Sec., Dr. Guy L. Connor, 707 Stroh Bldg., Detroit.

MINNESOTA: Minneapolis, Oct. 6-8. Sec., Dr. Thomas S. McDavitt, Lowry Bldg., St. Paul.

MISSOURI: Kansas City, Oct. 27-30. Sec., Dr. James Stewart, Jefferson City.

MONTANA: Helena, Oct. 6. Sec., Dr. S. A. Cooney, Power Bldg., Helena.

NEVADA: Carson City, Nov. 2. Sec., Dr. Simeon L. Lee, Carson City.

NEW JERSEY: Trenton, Oct. 20-21. Sec., Dr. Alex. Macalister, Trenton Trust Bldg., Trenton.

NEW MEXICO: Santa Fe, Oct. 12-13. Sec., Dr. W. T. Joyner, Roswell.

PHILIPPINE ISLANDS: Manila, Nov. 10. Sec., Dr. Jose V. Gloria, 686 Rizal Ave., Manila.

SOUTH CAROLINA: Columbia, Nov. 10. Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

UTAH: Salt Lake City, Oct. 6. Director of Regis., Mr. J. T. Hammond, 412 State Capitol Bldg., Salt Lake City.

WEST VIRGINIA: Charleston, Oct. 13. Sec., Dr. W. T. Henshaw, Charleston.

WYOMING: Cheyenne, Oct. 5-7. Sec., Dr. G. M. Anderson, State Capitol, Cheyenne.

Iowa June Examination

Mr. H. W. Grefe, director of examinations and licensure, Iowa Board of Medical Examiners, reports the written examination held at Iowa City, June 4-6, 1925. The examination covered 8 subjects and included 100 questions. An average of 75 per cent. was required to pass. Seventy-five candidates were examined, all of whom passed. Fourteen candidates were licensed by reciprocity. One candidate was licensed by endorsement of credentials. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
University of Illinois College of Medicine	(1925)	87.1, 92.9*
State University of Iowa College of Medicine	(1925)	83.4, 83,5, 84.6, 85.1, 86, 86.5, 86.6, 86.8, 86.9, 87, 87.1, 87.4, 87.4, 87.4, 87.4, 87.5, 87.5, 88, 88, 88.1, 88.4, 88.5, 88.7, 88.9, 88.9, 89, 89, 89.1, 89.1, 89.4, 89.5, 89.6, 89.6, 89.7, 89.7, 89.9, 90, 90, 90, 90, 90.1, 90.1, 90.1, 90.6, 90.6, 90.7, 90.7, 90.7, 90.7, 90.9, 91.1, 91.4, 91.4, 91.5, 91.5, 91.6, 91.7, 91.7, 91.7, 91.8, 92, 92.1, 92.1, 92.1, 92.1, 92.4, 92.6, 94.4, 94.7, 94.8, 95

Book Notices

The Medical Aspects of Chemical Warfare. By Edward B. Vedder, Lieut. Colonel, M. C., U. S. Army. With a Chapter on the Naval Medical Aspects of Chemical Warfare. By Duncan C. Walton, Lieut. Commander, M. C., U. S. Navy. Cloth. Price, $6.50. Pp. 327, with illustrations. Baltimore: Williams & Wilkins Company, 1925.

The purpose of this treatise is to bring before the medical officers of the United States Army, both regulars and reserve, information which they should possess on the medical aspects of chemical warfare. The introduction presents an excellent brief for this much maligned military weapon. It explains how gas warfare has suffered from Teutonic odium because it was first used by the Germans against defenseless troops. It explains how gas warfare has suffered also from the fact that gaseous weapons are new weapons and because the lay mind is especially sensitive to the somewhat mystic character of all things chemical. This introduction also brings out clearly that the public mind has been confused to a serious degree on this subject. This is in part a reflection of the early propaganda when the weapon was new and distinctly Teutonic, and partly the result of mere exaggeration by unscientific lecturers and writers. It is hard now for the public mind to accept that American made war gases are any more humane than German made gases. The subject has been further aggravated because organized pacifists who are unqualifiedly opposed to all militarism have chosen gas warfare as the most vulnerable point of attack against the military system. This is good generalship from the standpoint of the antimilitaristic movement, but it is poor science. The question of the humanity, effectiveness or economy of gaseous weapons cannot be judged from impressionistic premises. The only way to arrive at a true appraisal of this weapon is through a careful study of the records of the World War. Fortunately, these records are available in a high degree of accuracy, thanks to the excellent reports of the Surgeon General's Office. The authors present a careful analysis of these records and show conclusively that while gas proved to be a high casualty producer in the war, the fatalities were only about one twelfth of those resulting from other wound producing agencies. The text then proceeds to a technical classification of gaseous weapons into pulmonary irritants, vesicants, lacrimators and irritant smokes. Each gaseous weapon used in the World War is placed in its proper category and thoroughly discussed as to preparation, properties and treatment. The authors then take up the subject of protection against gas weapons, discussing successively the gas mask, protective clothing and collective protection. The rather perfunctory chapter on elementary physics and a second one on elementary chemistry scarcely comport with the vivid interest the rest of the subject matter carries. The final chapter discusses the somewhat mooted question of the treatment of certain respiratory diseases by chlorin.

The book measures up to the best expectations and is markedly free from irritating typographic errors. Its appearance at this time, when the Geneva protocol, seeking to ban gas warfare, is to come before our government for confirmation, is peculiarly timely. There are many thinking persons who have given careful study to this problem who believe that the banning of gas warfare will not advance the cause of universal peace. If universal peace is ever to be realized, it will come about, as Haldane has said, "By a careful scientific study of the causes of war." It is only in this manner that any advance has been made by science against disease, and war is a disease of society. It is not scientific, therefore, to seek to outlaw war by attempting to limit its methods. It is a grave question whether it is wise for any nation to forswear the use of such an effective weapon as military gas. The potentialities of such agencies become terrific against an unprotected country. Even the most sanguine exponents of the control of methods of warfare cannot maintain that agreements not to use this or that weapon can be made universal.

Chemical preparedness rests especially in a nation's industrial development. This comes about from the close resemblance, even identity, between industrial and military chemicals. The subject cannot be effectively controlled except by attempting to allocate the production of chemicals among the agreeing nations, so as to maintain a balance of chemical power. Such a program is fraught with immeasurable difficulties.

Any student with a sincere desire to learn the correct history of gas warfare will find a splendid opportunity in Vedder's book. To the reserve medical officer, it carries an especial appeal, because it assembles material on the action and treatment of war gases not available in any other collected source.

An Introduction to the Mind in Health and Disease. For Students and General Practitioners Interested in Mental Work. By T. Waddelow Smith, F.R.C.S., Deputy Medical Superintendent of the City Mental Hospital. Cloth. Price, $4. Pp. 235, with 6 illustrations. New York: William Wood & Company, 1925.

The author offers this book "in the hope that it may stimulate students in studying the many excellent textbooks now written on the subject and give a prop or two to the general practitioner in forming an opinion on the many cases of psychic origin, especially vagotonia, which come under his observation in his daily round." The introductory chapters contain several excellent colored diagrams; in addition, there is a fairly good outline of the vegetative nervous system. For the rest this book seems to be a collection of Freudian definitions—everything, from a corn to the gravest form of insanity is given a Freudian interpretation. The short paragraphs descriptive of the classic types of insanity are well done, but etiologic guesses are made at random. For instance, he says, "The origin of a large number of mental disorders is found in the disturbed equilibrium of the hormones of the organism as a whole." Again, in describing the mechanism of epilepsy, he says: "In studying the epileptic constitution one sees constantly a mixture of egotistic narcism and the drive of the paranoia dominating the conduct, until the epileptic dementia sets in, also an emotional tone circulating round the home and parents, which would strongly suggest that the infantile fixature was round the parent stage, and this is strengthened if we study the four classic cases of epilepsy in great men." This high-sounding explanation, which does not explain anything, is followed by instances in the lives of Napoleon, Dostoiefsky, Mahomet, Julius Caesar, who are considered by the author as proved epileptics. Napoleon's mother was a strong, arrogant, dominating personality, to whom he was devoted. Dostoiefsky idolized his mother and had an epileptic episode after her death when he heard her voice. Mahomet married a woman old enough to be his mother, to whom he remained true as against all the customs of the state in which he was living. And Julius Caesar is reported to have had constant incest dreams of his mother. Speaking of epilepsy, the author says: "The regression is interesting, for it seems to go back very far in the life of the individual to the stage of Magic 'Hallucinatory Omnipotence; of the race to probably our fish state, as the sense of smell is intensely repressed in these cases." These citations are self-condemnatory, and further comment seems unnecessary. Contrary to the author's expectation that his book may stimulate the further pursuit of similar studies, the tendency will be to confuse the reader with much unintelligible verbiage.

Forensic Medicine. A Text-Book for Students and Practitioners. by Sydney Smith, M.D., D.P.H , Principal Medico-Legal Expert, Egyptian Government Service. With an Introduction by Prof. Harvey Littlejohn, F R C.S., F R.S.E., Professor of Forensic Medicine, University of Edinburgh. Cloth. Price, $6. Pp. 498, with 117 illustrations. Philadelphia: P. Blakiston's Son & Co., 1925.

Human anatomy, physiology and pathology are the same the world over. So far as this book discusses matters determinable by those sciences, the fact that the discussion is based on the author's observation in Scotland, New Zealand and Egypt does not militate against its value in the United States. On the other hand, the very fact that the book is based largely on what the author has learned by experience gives to it, and especially to the illustrations, an unusual value. But there is no international uniformity of law or of legal principles, and this book as published in the United States seems to be merely a reprint of what was written for British dominions, based on British law. The American reader, therefore, must study with caution the chapters discussing points of law, or he may be badly misled. The book's chief value is in its discussion of identity, bodily injuries of all kinds, asphyxiation in its various forms, and the medicolegal relations of sex. These, however, are all discussed only from the standpoint of the criminal law. The discussion of mental disorders from a medical standpoint hardly gives a fair idea of prevailing concepts concerning them. Freud and psychanalysis are not mentioned, either to approve or to condemn. The discussion of poisons is brief and to the point, but it may be quesioned whether the analytic portions might not as well have been omitted. The chemist who must rely for his knowledge of analytic toxicology on so brief an account of it had better not assume the responsibility incident to such work.

An Introduction to Sexual Physiology. For Biological, Medical, and Agricultural Students By F. H A. Marshall, F.R.S. Cloth. Price, $2.75 net. Pp. 167, with 72 illustrations. New York: Longmans, Green & Co., 1925.

From such subjects as zoology, botany, anatomy, histology, embryology, physiology, obstetrics and sociology Dr. Marshall has constructed a compact volume. His treatment of the mechanism of reproduction begins with the ameba and ends with man. In discussing internal secretions of the reproductive organs, he touches on the rejuvenation operation of Steinach. The rôle of chromosomes leads him to the subject of inherited characteristics. In the last chapter, entitled "Fertility," he takes up vitamins, artificial insemination, the birth rate and the vexed question of birth control—his nearest approach to argumentation. The book is written in direct, finished, judicial style. It is crammed with information and excellently illustrated, partly in color. Too technical for the reader without a background in biology, it is not technical enough for the student of medicine. It would be interesting and fairly profitable reading for the summer before entering medical school.

Le bactériophage de d'Hérelle. Par Dr. Paul Hauduroy. Préface du Professeur Fernand Bezançon. Paper. Price, 10 francs. Pp. 212. Paris: E. Le François, 1925.

This little book gives a summary of the present knowledge of bacteriophages as viewed by the French followers of d'Hérelle. Consequently, bacteriophage is presented as a living agent or principle, a "virus of microbes," the discovery of which has opened the doors to new fields in science and new methods of treatment, the latter certainly being still in the earliest part of the experimental stage. The book is interesting as an introduction to the work on bacteriophage, but it cannot be accepted as containing any final solutions of the fundamental questions of the nature and significance of the bacteriophagic phenomenon.

Miscellany

REPORT OF MALARIA RESEARCH UNIT

In cooperation with the government of Palestine, the American Joint Distribution Committee maintains a malaria research unit at Haifa, which in 1923 conducted malaria control demonstrations to establish the possibility of malaria control at a low cost. The demonstrations provided information on the prevalence of malaria in Palestine and the types of mosquitoes and were an excellent means of educating the public in the value of malaria control. The engineering division of the research unit made detailed surveys of swamps and devised methods to eradicate them, demonstrating that many of the large swamps could be eliminated at no great expense. The Malaria Research Unit offered to contribute part of the cost of the work on condition that the inhabitants of the communities affected contributed the remainder, either in labor or in funds. The unit's laboratory examined thousands of blood films to determine the malaria index of communities and to establish diagnoses.

The topography and climate of Palestine make its malaria problem. There is a coastal plain from 4 to 20 miles wide from Acre to Gaza, which at Haifa turns east, cutting the hills transversely and joining the valley of the Jordan on the east with the coastal plain on the west. The hills between are chiefly limestone, in which winter rains erode deep holes and give rise to pools which retain water the year around As 'the rain waters approach the sea, they are blocked by sand dunes and spread out along the coastal plain into a series of great swamps known as coastal marshes. Rain seeps into the hills and crops out in the foothills as springs which flow on into neglected wadis. The inhabitants in the hills build cisterns to store up the rain. Thus the sources of mosquitoes are obvious. There are leaky irrigation ditches also, too shallow to hold all of the water and too pervious to prevent seepage. The irrigation ditch has become a serious problem. Stagnant water exists everywhere, but especially in the highlands and near the coast. These mosquito breeding places will be eradicated when the natives learn sanitation and when the country is developed, the cisterns fitted with pumps and the springs properly exploited. Coastal swamps can be controlled only by radical measures.

The research unit organized nine malaria control demonstrations, each with a trained antimalaria inspector, who lived in the district, supervised the breeding places and had assistants who visited the districts to instruct local inspectors. They reported weekly to the central office, which controlled all of the demonstrations. The total area under control was about 600 square kilometers with a population of 13,580 Jews and 7,650 Arabs, and all other classes of the population represented. There was (*a*) a house-to-house search for hibernating mosquitoes; (*b*) a survey of the parasite and spleen rates followed by treatment; (*c*) a complete survey of breeding places in a certain radius of settlements, and (*d*) control of breeding places. Quinin was used only when mosquito control had broken down and then only as a temporary measure. The larvicides that proved most useful were (1) a paraffin-crude oil mixture containing 0.1 per cent. castor oil; (2) Paris green, and (3) a water solution of cresol. The addition of castor oil to the kerosene mixture greatly increased its spreading and penetrating power and was more economical, as 10 c.c. is plenty for 1 square meter, whereas 25 c.c. of paraffin alone or paraffin and crude oil is required for the same area. Paris green was useful in overgrown pools where kerosene mixtures were almost useless. It was diluted with fine sand or road dust in the proportion of 1 part to 100; 10 gm. of this mixture was sufficient for 100 square meters of swamps; this did not kill the anopheles' eggs and pupae; consequently, the powder had to be applied every seven instead of ten days, as in the case of oil. For open reservoirs and irrigation wells in the orange groves, copper sulphate in a dilution of 1:1,000,000 was found sufficient to destroy the algae and keep the tank free from vegetation from three to four weeks.

The Bedouin and the shepherd come with their flocks from the East in the spring in search of pasture, move across the plains, settle along creeks, and change their camps frequently. They are usually heavily infected with malaria; the research unit found among them a parasite index as high as 25 per cent. and a spleen index of 80 per cent. or more. Thus, as they move from place to place they leave a trail of malaria behind them.

Prior to control work (in 1922), the minimum annual incidence of malaria in these areas was 50 per cent., and in at least three of the districts it was 100 per cent. The report shows the result of this control work graphically by tables prepared for the years just previous to the work and for the year 1923. There was a decided decrease in the incidence of malaria everywhere. In the Judea areas in 1923 there were practically no primary infections and relapses became fewer; extremely low rainfall in the winter of 1922-1923 facilitated the work. Progress was made in the Hedera district in 1923 until an explosive epidemic caused by an uncontrolled coastal marsh, 2.5 kilometers from the settlement, occurred in Hedera itself. The marsh was considered beyond the normal range of flight of mosquitoes, but the epidemic showed that plans for its control at a moderate cost had to be made. The Zichron Jacob area is skirted by the largest of the coastal marshes, and the control of mosquito breeding here was out of the question. Even in this area, there was a marked reduction in the incidence of malaria, achieved by (1) reduction of the number of carriers by intensive treatment; (2) eliminating breeding places in the immediate vicinity of settlements, and (3) systematic destruction of adult mosquitoes in houses. These "half measures" will not eliminate malaria in this area and eventually the Cabara swamps must be drained.

Taken as a whole, these demonstrations caused a notable reduction in malaria in seven of the nine demonstration areas, and while the amount varied in different areas, it was sufficient in all of them to indicate the possibility of malaria control. The average decrease for all the nine areas as compared with the incidence of malaria in 1922 was almost 50 per cent. The total cost of the work per control unit was about the same for all the districts since the salary of the malaria inspector was the principal item. The cost per capita varied, as a result of the varying density of population, and ranged from a minimum of 23 cents in Ekron to a maximum of $1.55 in Kinereth. These rates compare favorably with the cost of antimalaria demonstrations in the United States. The malaria research unit completed drainage operations in 1923 in the Ein Koreh seepage area, the Birket Atta Basin, at the spring east of the village of Yajur at Solim, the Wadi Little Zarain, the Jalud Swamp in the valley of Esdraelon, and the Wadi Wakkas in upper Galilee.

ANTIVACCINATIONIST DIES OF SMALLPOX

THE JOURNAL, September 26, contained a comment on smallpox statistics, pointing out that antivaccinationists were largely responsible for the increasing number of cases of this disease in the United States. *Health News* of the New York State Department of Health makes public the following instance:

> *Health News* of February 2 carried an item mentioning a fatal case of smallpox in a schoolteacher. An interesting feature of this case has just been brought to our attention by the health officer of the municipality in which the teacher lived.
>
> Following the teacher's death, mothers of two pupils in her class independently reported to the health officer that just before Christmas they had told the teacher that their children were to be vaccinated during the holidays. The teacher strongly advised against it on the ground that it "was a medieval custom, was harmful to the welfare of the child, and that deaths were occasionally caused by such vaccinations"
>
> On January 12 this teacher died of smallpox
>
> Although she took her own advice, fortunately the mothers of her pupils did not do so.

Medicolegal

Revocation of Registration for Assisting Unregistered Person in Practicing Medicine—Valid Law

(Davis v. Calderwood et al. (Mass.), 146 N. E. R. 708)

The Supreme Judicial Court of Massachusetts in deciding that a final decree should be entered dismissing the plaintiff's bill says that he sought by this suit in equity to enjoin the defendants, who constituted the board of registration in medicine, from proceeding with a hearing against him pursuant to a notice issued for him to show cause why his registration as a practitioner of medicine in that commonwealth should not be revoked. It is assumed that he would suffer irreparable injury in his property and personal rights if the defendants should proceed to revoke his registration, and that therefore in this suit he might question the constitutionality of the statute under which they were proceeding.

The statute regulating the practice of medicine and conferring powers of registration of physicians and of revocation of such registration for cause, has been before the court in numerous cases. Its constitutionality, although decided or assumed in all those decisions, was examined at large in *Lawrence* v. *Board of Registration in Medicine*, 239 Mass. 424, 132 N. E. 174. After a detailed analysis of the statute and a review of many authorities, its constitutionality was upheld. Further reflection affords no ground to doubt the soundness of that adjudication. It is affirmed.

The statute requires a hearing before a public board, at which this plaintiff may be represented by council and call witnesses, with provision for further hearing in court and for revision and reversal of the finding of the board if justice demands such action. Every constitutional right is protected. It was stated in the notice of hearing to be given this plaintiff that the specific charge against him was "alleged association with an unregistered person, to wit, James P. Coll, of 124 State Street, Springfield, Mass." Apparently this charge was framed under Section 2 of Chapter 112 of the General Laws of Massachusetts, whereby the board is empowered after hearing to "revoke any certificate issued by it and cancel for a period not exceeding one year the registration of any physician who has been shown at such hearing to have been guilty . . . of acting as principal or assistant in the carrying on of the practice of medicine by an unregistered person." The notice to be issued to a registered physician of such a hearing is not to be construed with technical strictness. It is to be assumed also that further specifications would be given on proper request in any instance when the subject-matter was not fairly set out in the initial notice. No such request appeared to have been made in the case at bar. Every presumption is to be made in favor of the regularity and fairness of the methods of procedure and of the proposed action of such a board.

The contention cannot be supported that assisting an unregistered person in practicing medicine is not a sufficient ground for the revocation or cancellation of a registration. Incidental means for enforcing and giving effect to a valid statute violate no constitutional rights. This provision stands on this point with the main provisions of the act.

Indictments and the Harrison Act—Tennessee Law

(Mitchell v. United States (U. S.), 3 Fed. R. (2d Series), 514)

The United States Circuit Court of Oppeals, Sixth Circuit, in affirming a judgment of conviction of defendant Mitchell for selling narcotics in violation of the Harrison Act, says that two counts of the indictment expressly alleged that the defendant was a physician and was duly registered as such under the Harrison act, and did not allege that his disposition of the narcotic stated was not made to a patient and in the course of the physician's professional practice. While it would not be necessary to negative this matter of lawfully dispensing in the course of professional practice if the counts had not already carefully shown that the defendant was a registered physician, yet, when this was made to appear, it then became necessary to negative, not an exception to something already stated, or an exception found in the act, but an inference naturally to be drawn from the acts which had been stated; and, as it has been decided that the giving of a prescription is participating in the sale made by the filler, the court cannot draw the necessary inference of nonprescription from the mere fact that the counts alleged selling. Therefore the court holds that these counts were insufficient.

Three other counts were not open to this objection; nor were they defective because they did not allege that the prescriptions were filled. They stated that the defendant, being a physician, sold, dispensed and distributed morphin in the following manner: That he issued a prescription therefor, not in the course of his professional practice. A physician who issues a prescription, which is filled, thereby participates in or aids and abets a sale. The allegation of sale or delivery implies a completed act, and when it is said that there was a sale through a prescription, it is, in effect, said that the prescription was filled.

At the time of the passage of the Harrison act it was believed by at least some reputable physicians that morphin addiction was a disease; that it was proper, in the treatment of this disease and to relieve pain and suffering, to prescribe morphin in limited quantities for these addicts; that to furnish the addict with a limited quantity of morphin for recurrent self-administration, even when the patient was not confined, was within the discretion of the physician; and that for a physician to furnish morphin in this way to an addict, when the physician in good faith believed it was necessary thus to treat the disease and relieve suffering, was a practice which was intended to be permitted by the express exemption found in the Harrison Act. In accordance with this idea, the Tennessee legislature passed a law intended to provide a system by which physicians who desired to do this kind of professional business would be measurably protected by what was, in effect, an official certificate that the morphin was necessary. As the construction of the Harrison act was developed by successive decisions of the Supreme Court of the United States it became apparent that this method was not within the stated exception, and that the practices approved of by some reputable physicians and expressly contemplated by the Tennessee statute were ipso facto (by the fact itself) violations of the Harrison act.

No Order for Excision of Cells or for Roentgenograms

(Andrus v. Fomfara (N. J.), 127 Atl. R. 788)

The Supreme Court of New Jersey says that in this action for damages the plaintiff contended that by reason of the defendant's negligence he was injured, and that a growth on the outside of his body, near the hip, was a result of such injury, and was a malignant and cancerous growth. The defendant desired not only to have the plaintiff examined by surgeons, but to have the order of examination provide that the surgeons might make an excision of some of the cells of the alleged cancerous growth sufficient in number to examine them under a microscope, contending that this was the best test to determine whether the growth was of a cancerous nature or not. If the court was not willing to direct that the plaintiff submit himself to an excision of a portion of the growth, then it was requested that the court direct that roentgenograms of the growth might be taken. If the court was unwilling to grant either of these requests, then the court was asked to make an order for an examination by surgeons without excision and without the making of roentgenograms. This application was made under Section 19 of the evidence act of New Jersey, which provides that on or before the trial of any action to recover damages for injury to the person the court may from time to time on the application of any party therein order an examination of the person injured as to the injury complained of, by a competent physician or physicians, surgeon or surgeons, in order to qualify the person or persons making the examination to testify in the case as to the nature, extent and probable duration of the injury complained of.

It will be observed that the statute gives to the court only the power to direct and order an examination of the person injured. The request of the defendant was for more than an examination. It amounted to a request for an operation. In this court's opinion the statute is not broad enough to give the court power to oblige a plaintiff to submit to an excision of cells from a growth in order to furnish testimony for the defendant, as to the nature of the plaintiff's ailment. No case was cited on the brief for the defendant which goes to this length. It has been held in compensation cases in New Jersey that an employee is not obliged to submit to an operation, even though physicians entertain the opinion that the operation would lessen the effect of the injury of the employee.

This court is also of the opinion that it should not direct that roentgenograms of the plaintiff be taken for the defendant. Roentgenograms sometimes result in the subject being seriously burned. In the case of *Boelter* v. *Ross Lumber Co.*, 103 Wis. 324, 79 N. W. 243, the plaintiff had submitted to an examination by the roentgen-ray process, and had been burned. The court refused to compel a second examination by such a process, and this was held not to be an abuse of the discretion of the court. In this court's opinion, the only examination which this court should permit and order was an examination without excision or the right to take roentgenograms.

Musculospiroparalysis Not an Accidental Injury

(Chop v. Swift & Co. (Kan.), 233 Pac. R. 800)

The Supreme Court of Kansas, in affirming a judgment for the defendant, says that the plaintiff was employed in a packing plant, carrying links of cold sausage from one part of the plant to another. She picked up the links with her right hand and draped them on her left arm, taking them to a carrier. The links of sausage were quite cold and the temperature of the room was low. Her arm became so cold that she said there was a numbness, and buckets of warm water had been provided into which she would thrust her left arm after the removal of the sausage, and then would return for another load. After she had been there for thirty days she had pains in her arm which she testified she first called rheumatism. She went to a physician who treated her and afterward noticed wrist drop. He diagnosed the affliction as one of musculospiroparalysis, and for musculospiroparalysis, or wrist drop, the plaintiff asked an award of compensation under the workmen's compensation law, but the court holds that the injury could not be regarded as an accidental one within the meaning of the law.

Society Proceedings

COMING MEETINGS

American Academy of Ophthalmology and Otolaryngology, Chicago, Oct. 20-24. Dr. Luther C. Peter, Chestnut and 20th Streets, Philadelphia, Secretary.

American Association of Railway Surgeons, Chicago, Oct. 21-23. Dr. Louis J. Mitchell, 29 East Madison Street, Chicago, Secretary.

American College of Radiology and Physiotherapy, Chicago, Oct. 19-22. Dr. Roy W. Fouts, 121 South 33d Street, Omaha, Neb., Secretary.

American College of Surgeons, Philadelphia, Oct. 26-30. Dr. Franklin H. Martin, 40 East Erie Street, Chicago, Director-General.

American Public Health Association, St. Louis, Oct. 19-22. Mr. Homer N. Calver, 370 Seventh Avenue, New York, Executive Secretary.

Association of Military Surgeons of the United States, New York, Oct. 8-10. Col. J. R. Kean, U. S. A. Ret., Army Medical Museum, Washington, D. C., Secretary.

Central Neuropsychiatric Association, Ann Arbor, Oct. 23-24. Dr. Karl A. Menninger, Neuropsychiatric Clinic, Topeka, Kan., Secretary.

Central States Pediatric Society, Chicago, November 6-7. Dr. H. T. Price, Westinghouse Building, Pittsburgh, Secretary.

Delaware State Medical Society, Wilmington, Oct. 13-14. Dr. W. O. La Motte, Industrial Trust Building, Wilmington, Secretary.

Interstate Postgraduate Assembly of America, St. Paul, Minn., Oct. 12-16. Dr. W. B. Peck, 82 Stephenson St., Freeport, Ill., Managing Director.

Kansas City Clinical Society, Kansas City, Mo., Oct. 5-9. Dr. James R. McVay, Rialto Building, Kansas City, Mo., Secretary.

Kentucky State Medical Association, Owensboro, Oct. 5-9. Dr. A. T. McCormack, 532 West Main Street, Louisville, Secretary.

Pennsylvania, Medical Society of the State of, Harrisburg, Oct. 5-8. Dr. Walter F. Donaldson, Jenkins Arcade, Pittsburgh, Secretary.

Southern Medical Association, Dallas, Texas, November 9-12. Mr. C. P. Loranz, Empire Bldg., Birmingham, Ala., Secretary.

Vermont State Medical Society, St. Johnsbury, Oct. 15-16. Dr. William G. Ricker, 29 Main Street, St. Johnsbury, Secretary.

Virginia, Medical Society of, Richmond, Oct. 13-16. Miss Agnes V. Edwards, 104½ West Grace Street, Richmond, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal for a period of three days. No foreign journals are available prior to 1920, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

American Journal of Electrotherapeutics and Radiology, New York

43: 301-326 (Aug.) 1925

Electrotherapeutics in Urology. V. C. Pedersen, New York.—p. 301.
History of American Electrotherapeutic Association. III. W. B. Snow, New York., and G. B. Massey, Philadelphia.—p. 307.

American Journal of Obstetrics and Gynecology, St. Louis

10: 153-312 (Aug.) 1925

*Cesarean Scar. O. H. Schwarz and R. Paddock, St. Louis.—p. 153.
*Weight and Dimensions of Human Placenta in Its Relation to Weight of New-Born Infant. F. L. Adair and H. Thelander, Minneapolis.—p. 172.
Preliminary Carcinoma of Cervix Uteri Treated with Radium in Woman's Hospital in State of New York. L. K. P. Farrar, New York.—p. 205.
*Gyneplastic Repairs Following Childbirth. J. L. Bubis, Cleveland.—p. 213.
Treatment of Secondary Anemia by Blood Transfusion Preceding Operation for Myoma Uteri and Pelvic Inflammatory Disease. B. M. Anspach and H. W. Jones, Philadelphia.—p. 222.
*Influencing Fertility of Female White Rat by Treatments with Placental Tissue. F. Kovacs, Baltimore.—p. 232.
Version; Indications and Contraindications. H. E. Miller, New Orleans.—p. 241.
*Symptoms Associated with Menstrual Cycle and Effects Thereon of Ovarian Therapy. H. Sharlit, J. A. Corscaden and W. G. Lyle, New York.—p. 246.
Rôle of Cervix in Sterility. I. W. Kahn, New York.—p. 254.
Limitations of Cesarean Section. C. J. Miller, New Orleans.—p. 260.
Brow Presentation an Attitude of Deflection; Case of Spontaneous Brow Transverse. D. A. Calhoun, Troy, N. Y.—p. 266.
Case of Uterus Duplex Bicornis with Double Vagina. J. W. Price, Louisville.—p. 269.

Cesarean Scar.—The healing of the incision in the wall of the guinea-pig uterus after abdominal hysterotomy is described by Schwarz and Paddock. It is concluded that the most important thing in the technic of elective cesarean section is to obtain good wound approximation with a minimum amount of suturing, with as little tension on the sutures as possible. A single row of buried interrupted sutures and an outer running suture after the method used by Williams should give the best results.

Relation of Size of Placenta to Baby.—Adair and Thelander report the results of a detailed study of 392 placentas. The main points bearing on the infant are: A positive correlation exists between the weight of the new-born and (*a*) the weight of the placenta; (*b*) the volume of the placenta, and (*c*) the surface area of the placenta. A low ratio of the weight of the baby to the weight of the placenta is found in prematures, very small babies which are really on the borderline of prematurity, and in pathologic cases, especially those where toxemia of pregnancy is present. A high ratio is found chiefly in postmature or large infants. A marginal insertion of the cord indicates a pathologic placenta and almost always means a small baby.

Gyneplastic Repairs After Childbirth.—Bubis urges to repair old lacerations of the genitalia shortly after childbirth. From an economic standpoint, it saves the patients, hospitals, and community many dollars and hospital days. Operative deliveries or the presence of lochia do not seem to interfere with the healing of the tissues. Subsequent deliveries are not complicated by the previous repairs. If a new laceration occurs, either spontaneously or by episiotomy, it is repaired *immediately after the delivery.*

Effect of Placental Tissue on Fertility.—Kovacs believes that he has established the fact that some important biologic change follows the parenteral introduction of fresh placental tissue into the female which results in a temporary checking of fertility.

Effect of Ovarian Therapy on Menstrual Cycle.—The clinical features and course in a group of 132 women who complained among other symptoms of hot and cold "flashes" and who received as therapy desiccated whole ovary are reported by Sharlit, Corscaden and Lyle. They have been most favorably impressed with the value of this therapy.

American Journal of Physiology, Baltimore

Studies on Radiated Proteins. I. Coagulation of Egg Albumin by Ultraviolet Light and Heat. J. H. Clark, Baltimore.—p. 649.
*Action of Epinephrin on Respiration. L. B. Nice and A. J. Neill, Norman, Okla.—p. 661.
Heat Regulation and Water Exchange. IX. Mechanism of Cold Anhydremia and Edema. H. G. Barbour and W. F. Hamilton, Louisville.—p. 665.
Beginning of Suprarenal Function in Embryo Chick. B. R. Lutz and M. A. Case, Boston.—p. 670.

Absorption of Undigested Protein from Alimentary Tract.—The experimental evidence obtained by Hettwer and Kirz support the assumption that an unusual increase of intra-intestinal pressure (as a result of stasis) is the essential factor in the absorption, and sufficiently rapid absorption, of an amount of undigested horse serum adequate to cause symptoms of anaphylactic shock in previously sensitized guinea-pigs, or to sensitize normal guinea-pigs, provided the dose is suitably adjusted.

Changes in Blood Pressure During Sleep.—Tracings of blood pressure were taken by Landis by the Erlanger method, together with auscultatory readings of systolic and diastolic pressure, while the subject went to sleep, during a short nap and during the period of awakening. As the subject went to sleep, the pressure gradually dropped from approximately 110 mm./74 mm. to 94 mm./68 mm. Certain of the curves assumed a definite pressure rhythm during this period. During sleep there appeared a more pronounced and more uniform pressure rhythm than when the subject was awake. Awakening as the result of sudden stimuli gave curves where the pressure rose very rapidly from a sleep level of 94 mm./68 mm. to 110 mm./74 mm. or higher. Natural awakening, other than that caused by sudden stimuli, was marked by a more gradual return to the normal waking pressure. Bodily position, whether reclining or semierect, had little or no effect on the blood pressure during sleep. This together with other considerations seem to indicate that the change in circulation is resultant from, rather than causative of sleep.

Action of Epinephrin on Respiration.—Nice and Neill state that within limits small doses of epinephrin injected into the blood stream of anesthetized cats, dogs and rabbits may cause an increase in the depth of respiration, while large doses produce a reversal effect or shallowness. There is a range in which the effects of epinephrin on respiration are independent of its influence on blood pressure. Large doses, however, invariably produce apnea and a rise in blood pressure. These results do not support the anemic theory.

American Journal of Roentgenology and Radium Therapy, New York

14: 105-206 (Aug.) 1925

Cholescystography by Oral Administration of Soluble Radiopaque Salts. C. S. Oakman, Ann Arbor, Mich.—p. 105.

Clinic Routine for Treatment of Syphilis. A. J. Casselman, Trenton, N. J.—p. 557.
Hyposulphite of Sodium in Treatment of Old Mercury and of Recent Years Arsenic Fast Syphilis. R. Wernigk, Los Angeles.—p. 563.
*Unilateral Wrist Drop Due to Syphilis; Cases. T. P. Murdock, Meriden, Conn.—p. 566.
Improved Graphic Form for Reporting Results of Kolmer's Quantitative Complement Fixation Test in Syphilis. R. A. Kilduffe, Atlantic City, N. J.—p. 569.

Sulpharsphenamin in Acquired Syphilis.—Fox gave sulpharsphenamin intramuscularly or subcutaneously in doses as high as 0.6 gm. without causing a significant local reaction, except in an occasional case, provided a solution of 33 per cent. concentration was used. The intramuscular or subcutaneous administration of the drug in patients in the secondary stage produced a slower healing effect on cutaneous and mucous lesions than is usually obtained with the other arsphenamins given intravenously. However, the end-results, as judged by absence of clinical recurrence and effect on serology, compare favorably with those produced by the other arsenicals. No superiority was shown for the drug in the treatment of patients with neurosyphilis, either when administered in the first instance or when given to patients known to be resistant to the other forms of treatment. Evidence was not obtained that the drug possessed particular value in reversing the serology of the Wassermann fast cases or in influencing favorably the clinical course of patients with disease of the cardiovascular system. The drug was found useful in treating three patients who had previously developed "shock" or "nitritoid" reactions after intravenous injections of the other arsphenamins. The route of administration seemed to play little or no part in determining the therapeutic effect, but was found to be of considerable importance as far as systemic toxic reactions were concerned. In this connection intramuscular injection was found to be the method of choice. Dermatitis was found to have a relatively high incidence, showing a total of six cases in 678 injections. It is important that three of these occurred among the 110 injections administered intravenously as compared with only one among 302 given intramuscularly. One patient, previously known to be intolerant to the other arsenicals, developed a severe grade of anemia of an aplastic type, but without purpura, following one course of seven subcutaneous treatments of 0.4 gm. each.

Sulpharsphenamin in Congenital Syphilis.—Dunham finds that sulpharsphenamin is a drug which has a distinct place in the treatment of congenital syphilis. It seems to be as effective an agent as neo-arsphenamin. There is a great advantage to the pediatrician in having at hand a form of arsenic which can be prepared easily and injected subcutaneously. It can be used in high concentration and local and general reactions need not be dreaded.

Noninfectivity of Blood in Syphilis.—Ten nonsyphilitic cases were transfused by McNamara from six syphilitic donors in the late stage of the disease. Four patients received one transfusion each, three received two, and three received three transfusions. One patient received blood from three donors. There was a marked improvement over the previous anemic condition in all cases. None of the recipients developed clinical evidence of syphilis or a positive Wassermann reaction during a period of observation of from sixteen to twenty-six weeks. From observations made on these cases and several others of which no accurate clinical record could be kept, *McNamara concludes that it is ordinarily safe to* use the blood of tertiary syphilitics for transfusion.

Arsenic Content of Spinal Fluid After Administration of Arsphenaminized Serum.—Six determinations of the arsenic content of the spinal fluid were made by Cornwall and Myers in a case of general paresis. On four occasions these determinations followed, at intervals of from six to thirteen days, the direct administration of arsphenamin to the spinal fluid. The arsenic averaged 16.77 mg. per hundred grams. On two occasions the administrations followed, at intervals of from four to eight days, the administration of arsphenamin in auto-arsphenaminized serum. No arsenic was present in one of these examinations and in the other the quantity was too small to be quantitatively determined but was detected qualitatively and, therefore, recorded as a trace.

Penetration of Arsenic into Spinal Fluid After Administration of Tryparsamide Intravenously.—Examination made by Fordyce and Myers of the spinal fluids from patients receiving the routine type of treatment with intravenous injections of tryparsamide showed that in this group 14 per cent. showed the absence of arsenic. The amounts of arsenic found do not exceed those found by other methods of administration. In order to obtain these results, it is necessary to introduce seven and one-half times as much drug as in other cases. In other words, the dosage is extremely large as compared with other drugs. Due to the rapid excretion of tryparsamide, the amount of arsenic available for penetration is extremely small after the twenty-four hour period. Experimentally, examination of the brain shows that nine times the arsenic concentration is maintained in the brain after silver arsphenamin with the use of one-fifteenth the amount of arsenic injected. It is shown that tryparsamide does not possess an unusual power of arsenic penetration into the central nervous system. Therapeutic penetration is hypothetical in that other factors which may enter into this condition are not available either experimentally or clinically.

Wound Healing in Syphilis.—Twenty-two surgical cases in which syphilis was present, as indicated by strongly positive Wassermann tests, are discussed by Menninger. Sixteen cases (72 per cent.) presented some difficulty in wound healing; the remaining six cases (28 per cent.) healed by primary union. Fourteen cases were infected in varying degrees (63.6 per cent.) five of which were potentially clean operative wounds. In four cases receiving preoperative treatment three presented some postoperative difficulty. All had positive Wassermann tests. Patients with syphilis as evidenced by a positive Wassermann test at the time of operation, despite the fact that they may have been treated, cannot be operated on with absolute impunity, although their postoperative course may be uneventful. Untreated cases of active syphilis may develop postoperative difficulty in wound healing. The rôle played by syphilis is not determined. In some cases pyogenic bacteria of low virulence grow luxuriantly; in others there is a poor tendency to union without gross infection; and in others, there is no postoperative *difficulty whatever.* Preoperative syphilitic treatment is desirable and postoperative treatment advisable, although the effectiveness of such treatment, so long as the Wassermann test remains positive, as an aid to the wound healing is undetermined.

Unilateral Wrist Drop Due to Syphilis.—Two cases of unilateral wrist drop due to syphilis are reported by Murdock. He feels that the condition is probably more common than was formerly believed.

*Acute Poliomyelitis; Detroit Epidemic. J. T. Watkins and E. D. McKenzie, Detroit.—p. 149.
*Etiology of Urticaria and Allied Dermatoses. F. J. Eichenlaub, Washington, D. C.—p. 170.

Pathology of Paralysis Agitans.—Two cases of paralysis agitans, one "idiopathic" and one postencephalitic, were studied in detail by Freeman. In each case there was severe degeneration of the substantia nigra without serious involvement of any other part of the brain. The findings in these two cases support Tretiakoff's contention that the substantia nigra is severely altered in paralysis agitans, and tend to show that this degeneration is the actual cause of the disease. The alterations in other parts of the brain were insignificant in comparison.

Mental Reactions as Sequelae of Epidemic Encephalitis.—In the ten cases reported by Silk there appears to be a definite relationship of influenza to the various syndromes presented. The so-called parkinsonian syndrome, which appeared following cases of typical attacks of lethargic encephalitis, did not differ clinically from cases in which no such attacks were observed. Influenza, however, was present in nearly all cases. It must, therefore, be regarded as either a very mild inflammatory process of the encephalon, which, though capable of producing such serious and lasting sequelae, passed practically unnoticed during its acute stage, or these sequelae are due to influenza and the so-called attacks of lethargic encephalitis as the more virulent forms of influenza of the cerebral type. In the cases of this series there was no tendency to improvement and in some the disease was rapidly progressive.

Epidemic Acute Poliomyelitis.—A total of 300 cases had been reported to about December 1, and a mortality of 14.67 per cent. returned in the Detroit epidemic of acute poliomyelitis which is analyzed by Watkins and McKenzie. Etiologic studies were conducted and confirmed by Rosenow's bacteriologic studies. In this group of cases those displaying spinal paralyses predominated numerically, as is true in most reported series; the bulbar group came next; those showing progressive ascending or descending involvement of the Landry type were third, as expressed by numbers, and lastly, cases with a predominance of cerebral and meningeal symptoms. The observations on the clinical pathology of the disease agree quite well with the pictures previously described. As to the end-results, there were thirty deaths. The cases presenting a predominance of cerebral symptoms with little peripheral neuron involvement contributed least to the mortality list and showed fewer residual paralyses. Of the bulbar group about 20 per cent. recovered. In these, disturbance of deglutition was the most outstanding feature when they left the hospital. Among the progressive group there were more deaths proportionately than in all other types. Aside from general measures immune homologous serum and Rosenow's immune horse serum were tried in about forty cases. Convalescent serum was collected on the twentieth day of the disease and inactivated, and nineteen cases were treated. Of this number, five, or 26.3 per cent., were apparently cured; 2, or 10.5 per cent., improved, and 12, or 63.1 per cent., showed no effect. The dosage employed was 20 c.c. repeated once, usually the following day. The intraspinal and intramuscular routes were the ones used. Intraspinally, 15 c.c. was the average dose. Rosenow's serum was employed in thirty cases and of this number, 16, or 53.33 per cent., were apparently cured; 3, or 10 per cent., were improved but would have recovered without it; 2, or 6.66 per cent., showed doubtful effects; 9, or 30 per cent., showed no change. Early the latter serum was adjudged of little value, probably because of the small doses used. The average was 20 c.c. total. Later, however, the dose was increased to five or ten times this amount and with this better results seemed to come. The intravenous and intramuscular routes of administration were the ones of choice.

Etiology of Urticaria.—Study by Eichenlaub of fifty-eight cases of chronic urticaria shows that nearly half of the cases (twenty-eight) were associated with other skin diseases. The probable etiology was determined in fifty cases. The therapeutic result in this group was directly proportionate to the ability to find and successfully treat the cause.

*Arteriovenous Fistula; Case. T. H. Thomason, Fort Worth, Texas.—p. 293.

Thrombosis and Embolism.—Vietor has studied twenty-one cases of fatal pulmonary embolism occurring in 12,615 operations. Necropsies were obtained in nine cases and showed a thrombosis of the femoral vein in four cases. In one case there was a thrombosis of the common iliac vein and the inferior vena cava. In two cases a wound inspection only was allowed so the condition of the femoral veins was undetermined. In the remaining two cases, while a complete necropsy was performed, no existing thrombosis could be demonstrated. The patients who died of a pulmonary embolus gave no clinical sign of a preexisting phlebitis or thrombosis, except in a case of carcinoma of the pancreas. In this case the patient had a hopeless condition and was gradually dying of a metastatic growth in his liver. On the thirteenth postoperative day a swelling of the left leg was first noted and on the twenty-seventh day hemiplegia developed. Death occurred on the thirty-first day after operation apparently from cachexia, but at necropsy a large pulmonary embolus with thrombosis of the common iliac and inferior vena cava was revealed. One patient with inguinal hernia complained of a pain in his right leg on his third postoperative day, but periodic examination was negative for clinical evidence of a phlebitis. He died on the eleventh day and at necropsy a thrombosis of the right femoral vein was found.

Intracranial Tumors Cause Communicating Hydrocephalus.—Pathologic evidence is offered by Dandy to show that hydrocephalus of the communicating type may be caused by tumors and abscesses when so situated that they obstruct the cisternal conduit under the brain stem. Postmortem injections of India ink proved the cisterna pontis to be completely blocked in each case. The cause of hydrocephalus in these cases is precisely the same as in the more common instances resulting from adhesions after the spontaneous cure of meningitis. All cases of hydrocephalus, whether of the communicating or noncommunicating type, have fundamentally the same underlying cause, an obstruction in the system of spaces through which cerebrospinal fluid circulates. The result of any such obstruction is reduction of the spaces in which cerebrospinal fluid is absorbed.

Epigastric Pain Symptom of Esophageal Obstruction.—Two cases are cited by Vinson which illustrate how the pain of cardiospasm may be confused with that of disease in the gallbladder.

Wandering Spleen with Torsion of Pedicle.—Sutton's patient, a boy aged 13, was awakened from a sound sleep by intense cramplike pain in the epigastrium. He vomited several times but the pain continued. During the morning a good bowel movement gave slight relief for a short time. Several hours before coming to the hospital, pain became more intense in the right lower abdominal quadrant. He was seen by his family physician, who made a diagnosis of "probable acute appendicitis." On the day prior to the onset of his abdominal pain the patient had a chill and an intensely sore throat developed. Up to the time of this illness he had attended school regularly, had done no violent exercise, and had not fallen or injured his abdomen. There was no history of previous abdominal pain, indigestion or constipation. His genito-urinary history was negative. The abdomen was flat, symmetrical and held rigidly throughout its entire extent. On palpation, there was acute tenderness in the region of the cecum and sudden release of pressure produced acute pain. Pressure over the splenic flexure of the colon did not produce pain at McBurney's point when the patient coughed. Across the entire lower abdomen the muscles were held very tensely and what appeared to be boardlike rigidity was present. No masses were recognized by abdominal palpation. A laparotomy was performed. Occupying and completely filling the pelvis was a mass which was recognized to be the spleen. It was enlarged to more than three times its normal size. The surface was smooth, glistening, free from fibrin or adhesions, and its color was bluish-black. The pedicle, on which it had rotated 360 degrees, was 10 inches long and looked like a large umbilical cord. No pulsations could be felt at the hilum of the spleen. The spleen was easily delivered from the pelvis and removed. The boy was well at the time of the last examination, four months later.

Ligation and Drop Treatment of Appendix Stump.—The ligation and drop method, leaving the stump free in the abdominal cavity, Maloney says, is the ideal procedure because it is more easily and readily performed with lessened mortality and morbidity rate. Any method of burying the stump in the cecal wall is unphysiologic and unsurgical and is followed by a greater percentage of complications and sequelae.

Hernia of Bladder.—In all inguinal and femoral hernias in people past middle life, Farr and Brunkow insist that the possibility of the involvement of the bladder should be kept in mind. In any case a positive diagnosis can be made by means of the roentgen ray.

Cysts of Iliopsoas Bursa.—Gatch and Green report one case and summarize the clinical data on affections of the iliopsoas bursa.

Femoral Arteriovenous Fistula.—A case of arteriovenous fistula of the femoral artery and vein is presented by Thomason showing Branham's sign and associated blood pressure variations, due to an increase in blood volume caused by the fistula; cardiac dilatation and hypertrophy—the result of increased volume flow-through the heart incident to the production of the fistula; slight dilatation of the proximal artery —due to the small size of the fistulous opening as compared to the cross section of the artery; marked development of the collateral circulation following formation of the fistula and unusual occurrence of auricular fibrillation three weeks after operation, ascribed to failure of the heart following damage to the myocardium at the time of repair of the fistula.

*Clinical Spirography. II. Bronchial Asthma. S. G. Mudd, Boston. —p. 345.
*Id. III. Variety of Respiratory Abnormalities. S. G. Mudd, Boston. —p. 349.

Spirography in Bronchial Asthma.—The type of breathing in the asthmatic patients studied by Mudd showed a prolongation of the expiratory phase in most cases. The expiration-inspiration ratio in cases of marked bronchial asthma varied from 1.5 to 2.1, as compared with an expiration-inspiration ratio of 1.3 to 1.5, in normal subjects. The respiratory records indicate the manner in which the breathing in asthma is facilitated by the use of epinephrin. The volume per breath is usually considerably increased, the respiratory rate reduced, the minute volume increased, and the expiration-inspiration ratio diminished following the injection of the drug. The vital capacity was increased in all instances. In one case the volume per breath was increased, the respiration rate greatly reduced, but the total ventilation was not greatly changed, following epinephrin. In a very severe case the expiration-inspiration ratio and the respiratory rate were not materially altered by the drug. The time required for the asthmatic to complete the supplemental phase during a vital capacity tracing was considerably prolonged, before as well as after epinephrin. In severe cases of asthma, the effect of epinephrin, even in large doses, was less marked and more transient in character than in mild cases. Atropin is of some value in the treatment of asthma; however, epinephrin is much more efficacious. Oxygen therapy is said to be of questionable value in asthma.

Spirography in Respiratory Abnormalities.—Respiratory tracings are reported on by Mudd of a number of respiratory abnormalities, including fracture of the sixth cervical vertebra, psychoneurosis, effort syndrome, lobar pneumonia, cardiac dyspnea, postoperative massive collapse of the lung, diabetic acidosis and uremic poisoning.

Determination of Kidney Function.—Agnew points out that there is such a wide margin of safety that incipient or slight changes in the kidneys are not indicated by tests. For instance, three fifths of the kidney tissue must be destroyed before the blood urea is raised. These tests are more to estimate the extent of the damage done. Also it should be remembered that focal nephritis may give albumin, pus and blood in the urine without in any way affecting the kidney function. This is due to the wide margin of safety provided by nature. It is a long way from the kidney to the eye, but an ophthalmoscopic examination is advisable in every suspected case. To study the retina is like holding a divided kidney in the hand.

Quinidin Sulphate in Heart Irregularities.—The results obtained from the use of quinidin sulphate in fifty-two cases of heart disease are presented by Jamieson. Of this number forty-nine were suffering from auricular fibrillation and three from paroxysmal tachycardia. The majority of the patients received a preliminary course of digitalis. Of the forty-nine cases of fibrillation, twenty-six reverted to normal rhythm. The permanence of normal rhythm was varied from a few days to two years. In the majority fibrillation has reappeared within several weeks; a number of this latter group have had two or more courses of treatment with varying success. Two patients have maintained a regular rhythm for a period of more than two years. Slightly better results were obtained in those patients in whom no valvular defect was demonstrated. Among this group there have been four deaths. Of the three patients who were treated for paroxysmal tachycardia, one received no benefit; a second was very markedly improved; the third, still under treatment, has had total freedom from an attack for seven weeks, which is an exceptionally long period for her. From a study of these results it would appear that in carefully selected cases the use of quinidin sulphate in the treatment of cardiac irregularities considered is justifiable. The most important contraindication would seem to be high grades of myocardial damage as demonstrated by either clinical or electrocardiographic examinations. The production of embolism following the use of quinidin is the danger which is emphasized. Judging from the fatal cases here reported, three of which came to necropsy, there must be some other factor, and probably the one suggested by Lewis, that with a changing rhythm there may be a ventricular standstill for a sufficiently long period to cause death, is the one to be feared.

Erythema Nodosum Result of Focal Infection.—Connell believes that erythema nodosum is a manifestation of focal streptococcal infection in which tonsils, teeth and nasal sinuses play the important rôle of infective foci.

Test for Hexylresorcinol in Body Fluids.—The test employed by Elliot and Barbour is a modification of one of the U. S. P. tests for resorcinol, some of which give no reaction for hexylresorcinol. To 2 c.c. of urine or fluid to be tested 0.25 c.c. each of 40 per cent. potassium hydroxid and chloroform is added. This mixture is boiled gently until one minute after the chloroform has been driven off. A pink color develops, usually strongest after standing for five minutes. When doubt exists as to the development of the color an unboiled control test should be performed. In distilled water hexylresorcinol can be detected in dilution of 1:100,000; in urine, 1:50,000; in serum, 1:25,000. If a 1:5,000 dilution of hexylresorcinol is added to bile, a pink color can be detected in the foam after the reagents have been boiled.

Adolescent Myxedema.—Davidson's patient was 17 years of age. Besides the myxedema she also had a nephrosis and tetany of parathyroid origin. She was treated successfully with thyroid and Collip's parathyroid extract. The patient died and a necropsy was made. No definite abnormality was found, except in the thyroid, parathyroids and kidneys. The postmortem findings are in agreement with the original diagnosis of subthyroidism, subparathyroidism and chronic nephrosis.

Atelectasis.—Farris reports seven cases to demonstrate that atelectasis of the lung occurs not infrequently, especially among patients in a tuberculosis institution, and that it is frequently confused with fibrosis.

Ultraviolet Ray Therapy of Tuberculosis.—Wright says that all forms of tuberculosis, except pulmonary and meningeal, are greatly improved by ultraviolet therapy. In active pulmonary tuberculosis and in tuberculous meningitis, ultraviolet therapy is contraindicated. Bone tuberculosis, skin tuberculosis, tuberculous adenitis, tuberculous peritonitis and pleurisy with effusion are among the forms most successfully treated. In the absence of heliotherapy, ultraviolet radiations from either the carbon arc or the mercury vapor lamp are the logical substitute; but, with artificial ultraviolet therapy, fresh air must be an important adjunct of the treatment. If it is felt in institutions particularly interested that heliotherapy itself must be applied, quartz window panes may be substituted for glass. After all, however, pure sunlight and fresh air are the real thing which artificial phototherapy is trying to imitate—and ignorance and greed may combine to form a so-called substitute for the ultraviolet ray which the superstitious and gullible public will accept as the real thing. The real use of these lamps, then, is to "carry on" when and where sunlight is not to be had.

Effect of Castration on Cancer Implantation.—Murphy and Sturm found that male and female mice castrated during the first seven weeks of life and implanted with cancer at later periods show a resistance definitely higher than do intact animals of the same age. This increased refractiveness is evident at three months after the operation but is more pronounced at from eight months to a year. Even castration in early adult life seems to increase the refractory state to later cancer inoculation. On the other hand, adult mice inoculated within a week after castration show slight, if any, evidence of increased resistance.

Influence of Nervous System on Function of Thyroid.—Crawford and Hartley assert that there is a marked individual variation in the histologic structure of the thyroid of rabbits examined at the same season under standard conditions. Although the microscopic appearance varies in different rabbits, the structure of the two lobes in the same animal does not differ. The variations are seen principally in the size and shape of the vesicles and in the quantity and character of the colloid. With one lobe as a control no histologic changes in the other lobe had been observed following section or stimulation of either the cervical sympathetic or the vagus and its branches.

Histologic Changes in Thyroid Following Lobectomy.—The changes which took place in the histology of the left lobe of the thyroid after excision of the right lobe have been studied by Crawford and Hartley at varied intervals of time. Two days after the removal of one lobe the other lobe showed a slightly increased colloid content, an increased vacuolation of the colloid, and a slight increase in the size of the epithelial cells. At the end of a week, the vesicles were greatly increased in size, distended with colloid, and the epithelial cells were flattened, while after three or four months signs of compensatory hypertrophy were present. The changes observed were uninfluenced by division of the vagus or cervical sympathetic.

Function of Macrophages in Resistance to Infection.—Nakahara demonstrates the ability of macrophages to dispose of pathogenic bacteria with but slight, if any, cooperation of polymorphonuclear elements.

Relation of Ovary to Fat Metabolism.—Burrows and Johnston are convinced that the follicular fluid of the ovary contains an active growth-stimulating substance and one capable of initiating an active digestion of a foreign fat, which might otherwise remain unabsorbed for an indefinite time in the tissues of these animals. Whether this substance exciting growth and a digestion of the oil is the same or in any way related to the substance exciting estrus in these animals was not determined. That it may be a different substance from the estrus-exciting substance is suggested, however, by the fact that a similar excitant of growth and fat digestion has recently been extracted by the same method from the corpus luteum of pigs. These extracts of corpora lutea have not excited estrus in spayed rats.

Relation of Vitamins to Tissue Reaction to Injury.—Jorstad has studied the tissue changes produced by coal tar. Drops of coal tar introduced into the subcutaneous tissue attract the fibroblasts, endothelial and other cells to them. These cells suffer degenerative changes through this action of the tar and the animal suffers cachectic-like changes and death from large doses of it introduced into the subcutaneous tissue. This action of the coal tar is limited to a short period of time, after which it becomes inert. The cells which have been drawn to it and which have not completely degenerated then slowly recover. Where large numbers of these cells are drawn to the tar, they grow and divide after recovering from the initial effects of the tar. Cancer may develop. Where only a few cells are drawn to the tar they lay down intercellular fibrils and a scar eventually develops. Vitamin A, fed in more than ample quantities to these animals, protects the animals and the cells against the toxic action of the tar and stimulates and prolongs their secondary growth. Vitamin B stimulates the secondary growth of these cells. This action is limited in extent and time. It is followed by an early degeneration and hyalinization of the tissue.

*Metabolic Observations in Psychiatric Cases. J. W. Sherrill, Morristown, N. J.—p. 129.

Diabetic Coma Complicated by Tuberculous Pneumothorax.—Some unusual clinical features of the case reported by Waters and Ruby are the recent occurrence of pneumothorax as a probable factor in precipitating coma, and the rapid recovery from the pneumothorax under diabetic treatment. The favorable progress of the tuberculosis under insulin treatment is similar to that already reported by a number of authors. As far as is known, the dosage of 450 units of *insulin is among the highest that has ever been given in* twenty-four hours to any patient who has recovered. The recovery of tolerance in such a case, to a point at which an adequate diet could be assimilated without need for insulin, is also noteworthy.

Metabolism in Psychiatric Cases.—The results obtained by Sherrill as regards suspected primary or secondary metabolic disorders in psychiatric cases and the therapeutic influence of various diets may be summed up under the following three heads: (1) Carbohydrate metabolism.—Blood sugar analyses and glucose tolerance tests in the miscellaneous forms of insanity gave results not specially different from those to be found in sane persons. No disturbance of carbohydrate metabolism was demonstrable as specifically connected with any form of nervous disease. (2) Chlorid metabolism.—The figures for plasma chlorids in the various types of insanity were similar to those found in normal persons or in other classes of patients. Strict chlorid free diets continued from fourteen to seventy-nine days gave no therapeutic benefits in dementia praecox, manic-depressive insanity, involutional melancholia, or epilepsy. (3) Fasting for epilepsy.—Four epileptics were subjected to complete fasting for two weeks. The seizures appeared to be diminished during the fast in most of the cases (though apparently aggravated in one case). No real therapeutic benefit resulted. In general, therefore, the chemical and dietetic methods here used have thrown no light upon the etiology, nature, diagnosis or treatment of nervous and mental disorders.

Tuberculous Splenomegaly.—One of these patients was aged 65. There was but a five weeks' history of progressive wasting and muscular weakness, with no particular complaint or symptoms other than those due to the presence of the splenic tumor. She had noticed for two or three years that her abdomen was getting bigger. The tumor filled the whole left upper and lower quadrants and the right lower quadrant of the abdomen. The right side of the tumor, on which the notch was recognizable, was somewhat mobile, while the left side of it seemed to be deeply anchored. Splenectomy was performed. The woman died on the fourth day. The only evidence of tuberculosis was found in the spleen. The second patient was only 28. Her symptoms were of six months' duration The spleen, firm and apparently smooth to the touch, occupied the whole left side of the abdomen, to 3 or 3½ inches below the umbilicus. Splenectomy was performed. For some weeks after discharge the patient picked up nicely, but she died six months later of generalized tuberculosis. In considering these two spleens, Carling and Hicks found that they had certain characteristic features in common, but presented certain well marked differences. A feature common to both was vascularity, with a change of the ordinary splenic structure into that of a moderately loose-meshed sponge, of which the interstices were for the most part filled with blood. Another similarity was a general increase in the interstitial fibrous connective tissue. In both spleens, some typical "giant cell" formations were found. From a surgical point of view the conclusion to be drawn from a study of these cases is that splenectomy should be performed early, and that irregular fever with splenomegaly should suggest tuberculosis.

Use of Blood Serum of Dengue Patients in Treatment of Splenomegaly in Chronic Malaria.—Being fully convinced that some antitoxin is formed in the blood of persons who have suffered from true dengue fever, which has a destructive action on the malaria parasite, Ingram-Johnson obtained a serum from the blood of persons just recovered from true dengue and experimented with it by intramuscular injection on children with chronic splenomegaly. In three cases cited the spleen receded to normal size. Ingram-Johnson suggested that by injections of this vaccine, artificial immunity from malaria can be procured The vaccine having such an effect on malaria parasites present in the circulation (even though not causing acute attacks of malaria) should, by its presence in the blood, prevent the proliferation of parasites injected into the blood as sporozoites by infected anopheles and hence should act as a prophylactic against the disease.

Levulose Test for Liver Efficiency in Mental Cases.—A summary of the results obtained at the Belfast Mental Hospital last year shows that out of fifty-five unselected cases of general paralysis in all stages of the disease, 36 per cent. were considerably improved and suitable for discharge. All these cases showed marked psychic improvement, but this improvement was not accompanied by a parallel one in the *physical signs* Serologically the improvement was less obvious. Apoplectiform seizures following the treatment were conspicuous by their absence. Complications are negligible and fatalities due to the treatment average not more than 10 per cent.—a percentage somewhat higher than the average of other workers. Graham says that malarial treatment is the more beneficial the earlier it is instituted in the course of the disease, and that it undoubtedly offers the best prospects of any treatment so far available of brightening the outlook in cases of general paralysis of the insane.

Puerperal Sepsis.—This report is based on analyses of 249 cases, with recovery in 160 and death in eighty-nine. The analysis made of these cases suggests that the following should be considered to be of grave significance: (1) Onset of pyrexia during labor or within twenty-four hours of its termination. (2) Extensive tissue damage in the labor, particularly tearing of vagina and cervix rather than of perineum only. (3) Presence of streptococci in the blood. (4) Persistently high pulse rate. (5) Insomnia. (6) Diarrhea with or without general peritonitis. (7) General peritonitis, pneumonia, or delirium. Signs and symptoms of good prognostic significance are: (1) Absence of streptococci in the blood. (2) Moderately low pulse rate, about 120. (3) *Freedom* from insomnia and diarrhea.

Premature Separation of Normally Implanted Placenta.—Williams reports a fatal case of separation of the normally implanted placenta with concealed hemorrhage, in which the amount of blood lost was insufficient to account for the symptoms of shock, and in which necropsy failed to show the existence of toxemic lesions. The natural history of the accident in a series of forty cases is considered, and details are given of a patient who suffered from it in two successive pregnancies. Antepartum hemorrhage is almost as frequently associated with premature separation as with placenta praevia, fifty-seven and sixty-four cases, respectively, of the two conditions having been noted in 9,000 consecutive admissions. The prognosis is serious for the mother and alarming for the child, the mortality being 7.5 and 75.5 per cent., respectively. Most severe cases are associated with the uteroplacental apoplexy of Couvelaire, but not always. In many of the severe cases, preeclamptic toxemia, eclampsia, chronic nephritis or "essential hypertension" precede or accompany the accident. But in fifteen of the thirty-seven patients who survived delivery, albuminuria was entirely absent during the puerperium. If many of the severe cases are the result of a toxemia, Williams says, it must be admitted that its origin and mode of action are unknown. Evidence is adduced to show that traumatism, syphilis, inflammation of the decidua, shortness of the umbilical cord, and torsion of the pregnant uterus are rarely, if ever, concerned in the production of the accident. Ligneous consistence of the uterus was observed in about every third case. When present it is a pathognomonic sign, but its absence does not accord equally valuable negative evidence.

Inversion of Uterus.—McCullagh reports on three cases and gives the results of an analysis of 233 recently recorded cases, of which number 200 were associated with labor and thirty-three were due to tumor, i. e., 85 per cent. were puerperal.

Acute Puerperal Fever.—Among the fifty-seven cases of acute puerperal fever reviewed by FitzGibbon and Bigger in this paper, there were twenty-nine deaths, or 51 per cent. During the four years from which these infected cases were collected, there were 14,380 confinements attended, and of these forty appear as acute puerperal sepsis with sixteen deaths; this gives an incidence of infection of 2.8 per thousand and a mortality of 1.1 per thousand.

Etiology of Puerperal Sepsis.—Streptococci were found by Bigger and FitzGibbon in the vagina before and after delivery in 68 per cent. of the cases examined. Hemolytic streptococci were only found twice in the examination of 108 vaginal swabs. *Streptococcus pyogenes* was never found. The predominant nonhemolytic streptococci of the vagina were *S. fecalis* and *S. mitis*. Nonhemolytic streptococci were present in the postpartum uterus in at least 20 per cent. of the cases examined. The authors suggest that the commonest form of puerperal sepsis, that caused by hemolytic streptococci (and particularly *Streptococcus pyogenes)* is due to exogenous infection. Nonhemolytic streptococci occasionally cause puerperal sepsis.

Results from Gilliam Operation.—Solomons asserts that properly performed subperitoneal operation will cure the symptoms in nearly all cases of backward displacement of the uterus, whether mobile or fixed. There will be no postoperative complications nor trouble in labor. Furthermore, there can be no comparison between a subperitoneal shortening of the ligaments, and either an intraperitoneal shortening or any direct uterine suspension. The first is safe; the two last styles are fraught with dangerous possibilities.

Yellow Fever Epidemic in Salvador.—Among nineteen persons who had recovered from clinically positive yellow fever in San Salvador, in 1924, in sixteen (84 per cent.) the serum gave a positive Pfeiffer test. Of five persons from the western part of the republic, who had passed through a disease which was clinically suspicious of yellow fever, the serum of two gave positive reactions. The tentative diagnosis of yellow fever in these two cases was thus confirmed by the Pfeiffer test. The serum of fifteen soldiers who had lived in San Salvador and in the same barracks where yellow fever had occurred gave negative reactions. Fifteen normal sanitary inspectors who had no history of yellow fever gave negative Pfeiffer reactions, while the test was positive in the case of one inspector who had had yellow fever in Peru four years previously. Twenty-two children, from 6 to 8 years of age, who had lived in San Salvador during the epidemic, all gave negative Pfeiffer reactions. Pfeiffer tests of the serum of vaccinated but otherwise normal persons showed that in some instances the lytic substances induced by vaccination may still be active against *Leptospira icteroides* after a lapse of five months. The pathologic findings in six cases of yellow fever are presented by Muller and Blaisdell. In the liver, zonal necrosis was present, and, more rarely, focal necrosis, together with marked fatty degeneration. Associated with these changes was a round cell infiltration and a milder polymorphonuclear infiltration. Mitosis and hemorrhages were frequently found. In the kidney there was evidence of acute tubular nephritis of varying intensity. Lime casts were present in two of the six cases. Their appearance suggested that they originated from desquamated epithelial cells which had become calcified. The suggestion is offered that lime casts are found in some but not all types of nephritis associated with yellow fever, occurring especially when desquamation is a feature.

Anemone Transvaalensis.—The natives of the Helspruit district, and also Europeans, use this wild plant to relieve headache by crushing some fresh leaves in the hand and inhaling the vapor. A decoction, made by boiling the leaves and roots in water, is used as a lotion to wash festering wounds and to relieve poisonous bites. Brandwyk and Watt report on its pharmacology. The leaves of *Anemone transvaalensis,* when fresh, are irritating and produce blistering on the skin. This action is due to the presence of anemonol, which readily decomposes into anemonin and iso-anemonic acid, both of which are nonirritating. Its local action is too drastic, too penetrating and too slow for use in medicine, and is inferior to that of cantharis. The irritating properties of the plant are quickly and easily lost on drying. Chemically and pharmacologically, *Anemone transvaalensis* resembles very closely other irritating *Ranunculacae.* The use of a decoction seems illogical, as it is nonirritating and contains neither tannic acid nor alkaloids which might exert a local action.

Vaccination of Monkeys Against Tuberculosis.—Wilbert's article was reviewed editorially September 12, page 826.

Experimental Putrid Infection; Causal Factors and Therapy.—Weinberg and Ginsbourg's experiments consisted in inducing lesions of putrefaction in guinea-pigs. The process appears to be due to histolysis by bacilli, accompanied with formation of fetid substances. The principal proteolytic bacillus involved is *B. sporogenes*. The bacilli are associated with one or several toxic, nonproteolytic bacilli. An essential putrid infection is rare; frequently it complicates an acute or chronic infection of different nature. Usually several tissues are affected; sometimes the lesions are chiefly located in muscle or exclusively in skin and the subcutaneous cellular tissue. The lesions of the tissues may not be extensive, even when the fetidity is very pronounced; this occurs in putrid peritonitis or pleuritis. Grave lesions from putrefaction-inducing bacilli disappear spontaneously, if the bacilli are only slightly pathogenic. The authors assert that putrid infection is easily controlled by intravenous injections of specific serums against all the bacilli involved or, at least, against the predominant bacillus. The injection should precede an operation for removal of a gangrenous appendix, or gangrenous focus in the lung. Postsurgical complications may be avoided with the preliminary serotherapy.

Congenital Syphilis Roused by Pregnancy.—Récamier treated four women, aged from 20 to 28 years, who first presented signs of syphilitic infection after the birth of the first baby. None of the women had an abortion, and the infants were normal. Investigation revealed that the fathers of the four women had a history of syphilis. The pregnancy seemed to have awakened the latent congenital syphilis. The efficiency of the specific treatment confirmed the diagnosis.

Lamblia in the Gallbladder; Three Cases. Labbé and Nepveux.—p. 609.

Diagnostic Value of Albumin in Duodenal Juice.—No albumin was found in the duodenal juice of eight healthy persons, examined by Simici and Téodoru. In seventeen cases of catarrhal jaundice, albumin was constantly present in the duodenal juice. The amount of albumin was larger in the beginning of the disease than at the end, but it persisted during convalescence, after other symptoms had disappeared. Albumin was found in the duodenal juice of five patients with jaundice from arsphenamin treatment; in three cases of angiocholitis; in two of hypertrophic cirrhosis of the liver, and in two of grave anemia—all associated with jaundice. Albumin was noted also in two patients with chronic constipation and in one with a tenia, without jaundice. Changes in the liver cell and its membrane are probably responsible for the passage of albumin. In catarrhal jaundice, the lesion of the hepatic cell is more important than the inflammation of the biliary ducts, since the increase of albumin is not accompanied by increase of mucin. Examination of duodenal juice for albumin may reveal a slight deficiency of the liver cell, clinically masked.

False Gastric Crises.—Tabes had been diagnosed in the old syphilitic, but the trouble proved to be a duodenal ulcer, cured by gastro-enterostomy.

Treatment of Epidemic Poliomyelitis. Delherm and Laquerrière.—p. 329.

Action of Roentgen Ray on Cancer of Lymphocytoma Type.—Belot and his co-workers treated, during the course of a year, a tuberculous woman, aged 47, with fifty-eight tumors of this type, the size ranging from that of a nut to a large fist. They exposed each tumor in turn, and each became reduced in size by a third in eighteen hours after exposure to from 8 to 10 roentgen units, and had clinically disappeared by the fourth day. No toxic phenomena were noted, although two or three tumors were treated each week. A lymphocytoma which developed in the orbit two years later was also exposed to 10 roentgen units, and the tumor and secondary exophthalmos subsided in five days. In one of several other lymphocytoma cases a tumor of the breast disappeared under 15 units in twelve days, and tumors of the face and chest in a few days. Under exposure to 20 roentgen units a tumor in a man's axilla disappeared in five days, and one in the thyroid region in eight days. This patient died six months later, probably from a deep tumor in the thorax. Obviously the prognosis of the disease is still grave, since recurrences and metastases are frequent. The serial microscopic findings in the first case confirmed the destruction of the cancer cells by the rays, the intense diapedesis of macrophages, and the intense phagocytosis.

*Autoserotherapy in Epidemic Encephalitis. D. Paulian.—p. 945.
Heart of Double Monsters. F. Corsy.—p. 956.

Intraspinal Injections of Autoserum in Treatment of Epidemic Encephalitis.—Paulian applied this method in acute encephalitis and in over thirty patients with postencephalitic parkinsonism. From 40 to 50 c.c. of blood were withdrawn, and the serum inactivated at 56 C. A dose of 10 or 15 c.c. was injected intraspinally, after an equal amount of cerebrospinal fluid had been removed. The patient then reclined (without pillow) for twenty-four hours. In two cases, among others, of acute encephalitis in young girls, a single injection was followed by improvement the next day, and complete recovery of one patient the fifth day. In cases of postencephalitic sequelae from one to six injections were required; sometimes the injections were resumed after three months, and then given daily for three months. Change in the attitude and facial expression, and reappearance of the automatic movements of the arms, in walking, were noted after the first injection. The recovery has persisted in eight patients for several months to date; in others a considerable amelioration was manifest. In several cases intravenous injections of 5 c.c. of a 25 per cent. solution of sodium salicylate were given supplementary to the intraspinal autoserotherapy. He queries whether the autoserum induces an intensive reaction in the nervous centers and a certain immunity, or whether the serum contains specific antibodies against the disease.

Tuberculosis and Nocardiosis. H. Gougerot.—p. 1121.
*Hemotherapy in Psychoses. Pascal and Davesne.—p. 1126.

Hemotherapy in Mental Disorders.—Pascal and Davesne treated by injections of whole blood three patients with a grave form of dementia praecox and three with an acute form of hebephrenia and catatonia. The blood was taken from insane patients during a period of remission induced by hemotherapy, nuclein or turpentine shock. In five instances the blood groups corresponded with those of the patients. Six intramuscular injections, each of 20 c.c. of blood, were given at two day intervals, before meals. Sometimes 5 or 10 c.c. were given in the first injection, 15 or 20 c.c. in the next. No complications were noted with the treatment. Two patients recovered; in three the psychosis temporarily improved. In one case the result was negative. This blood injection treatment may be indicated for the insane with insufficient nourishment and poor general condition; also in women with irregular menses. It seems to be the treatment of choice in different forms of melancholia, and in compensating the mineral deficiency in maniacal conditions.

Metabolism Under Reduced Atmospheric Pressure.—Ehrlich presented convincing experimental evidence for the theory that arsenic compounds are toxic for the animal organism only when the arsenic is in the trivalent state. On the basis of this theory, Jaquet took the minimal lethal dose of pentavalent arsenicals (atoxyl and sodium cacodylate) as a means to measure the reduction processes in the rabbit under various atmospheric pressures. He found that under a pressure which is equal to an altitude of 1,800 meters, the lethal dose of these arsenicals is reduced by 22-23 per cent. as compared to the lethal dose under 760 mm. pressure. This demonstrates that even at an altitude which usually does not produce any subjective symptoms, the metabolic processes are altered.

*The Combined Sugar in Diabetes. V. Bisceglie.—p. 215.
*Syphilis of the Stomach. Luigi Ajello.—p. 227.
Experimental Lead Poisoning. Luigi Scremin.—p. 244.
*Chronic Infectious Endocarditis. A. Ceresoli.—p. 256.

The Combined Sugar in Diabetes.—Bisceglie reports experiences which confirm that the absolute and proportional amounts of the combined sugar in relation to the free sugar in the blood are doubled in diabetes. This is even more pronounced under the influence of insulin; as the free sugar drops, the relative amount of combined sugar increases. The hypoglycemia from insulin may be due in part to the transformation of the free sugar into the combined form.

Syphilis of the Stomach.—Ajello analyzes the necropsy records in the literature, classifying under seven headings the manifestations of syphilis in the stomach. A case described in detail presented a nodular sclerogummatous infiltration.

Chronic Infectious Endocarditis.—Ceresoli adds nine new cases of endocarditis lenta to the sixty already published in Italy. He confirms the etiologic importance of *Streptococcus viridans*, and the well defined clinical and histologic findings of this morbid entity.

*Pneumothorax Treatment of Bronchitis. A. De Martini.—p. 697.
*Early Syphilitic Meningitis. Guido Milani.—p. 701.
*Malaria. M. Battaglia.—p. 705.
*Colloidal Extracts of Tubercle Bacilli. A. Grimberg.—p. 706.

Bilateral Pneumothorax in Treatment of Chronic Catarrhal Bronchitis.—De Martini reasons that an artificial pneumothorax would tend to immobilize the inflamed walls of the bronchi and give them a chance to heal. The sputum dropped from 200 to 60 c.c. in five weeks in one man. From 85 to 201 c.c. of the gas were introduced into the pleura on each side at each sitting as a rule. The intervals were from days to a week, and this pneumothorax treatment was kept up for five months, the sputum then 50 c.c.

Syphilitic Meningitis.—A recently infected young woman developed acute and severe syphilitic leptomeningitis. She recovered promptly under specific treatment except that the strabismus persisted for a few months.

Unusual Manifestations of Malaria.—Battaglia has had cases in which the absence of choked disk was the only puzzling element of a supposed brain tumor syndrome. In other cases the malaria induced intermittent psychopathies and cerebellar disturbances, the gait so altered that drunkenness was often assumed. Cases like these may develop insidiously, with little or no fever at first. Neuropathic disturbances of malarial origin are exceptionally tenacious. One of his patients presented all the symptoms of a sudden cerebral hemorrhage except that there was no conjugate deviation of the eyes. One malaria patient presented aphasia with right hemiplegia, as the fever ran high in an attack. Both in acute and in chronic malaria, changes in the walls of the vessels are common, up to diffuse arteriosclerosis. Aneurysm, on the other hand, he never found in malaria cadavers, probably because the blood pressure is generally low in malaria.

Treatment of External Tuberculosis.—Grimberg reports an additional series of 225 cases in which treatment was with his colloidal suspension of tubercle bacilli particles, triturated with iron filings in a magnetic field.

History of the Lima Medical School. H. Valdizan. Supplement.—pp. 1-88.

Insanity in the Indians of Peru.—Valdizan remarks that comparatively few Indians are found in the asylums of Peru. The records of the Hospicio de Insanos at Lima, from 1859 to 1917, show only 535 Indian inmates, including 232 women. The age of the majority was between 16 and 25, and 74.27 per cent. were unmarried. The most frequent psychoses were the toxic (23.17 per cent.); manic-depressive (21.80 per cent.); epilepsy (12.85 per cent.), and idiocy (6.33 per cent.). Valdizan adds that these figures are not really dependable as the Indians often conceal the fact of their race, claiming to be white. The old writers commented on the mildness of insanity in Peru. Dementia praecox in the Indian race is characterized by delirium based on legend and the history of the country

Congenital Malformation of the Female Genital Organs.—Nineteen cases are described. The external malformations predominated. These atresias induce hematometria, hematocolpos, etc.

Tuberculosis and Nocardiosis. H. Gougerot.—p. 1121.
*Hemotherapy in Psychoses. Pascal and Davesne.—p. 1126.

Hemotherapy in Mental Disorders.—Pascal and Davesne treated by injections of whole blood three patients with a grave form of dementia praecox and three with an acute form of hebephrenia and catatonia. The blood was taken from insane patients during a period of remission induced by hemotherapy, nuclein or turpentine shock. In five instances the blood groups corresponded with those of the patients. Six intramuscular injections, each of 20 c.c. of blood, were given at two day intervals, before meals. Sometimes 5 or 10 c.c. were given in the first injection, 15 or 20 c.c. in the next. No complications were noted with the treatment. Two patients recovered; in three the psychosis temporarily improved. In one case the result was negative. This blood injection treatment may be indicated for the insane with insufficient nourishment and poor general condition; also in women with irregular menses. It seems to be the treatment of choice in different forms of melancholia, and in compensating the mineral deficiency in maniacal conditions.

*Sedimentation Test in Tuberculosis. Willy Racine.—p. 556.
*Peritonitis from Pancreatitis. L. Choquard.—p. 590.

Sedimentation Test in Pulmonary Tuberculosis.—Racine's 406 monthly tests on 106 subjects at Leysin confirmed that regularly accelerated speed is an unfavorable omen. The extent of the pathologic process and the progressing character of the lesion determine the state of the balance between the forces of molecular attraction and of electric repulsion of the erythrocytes.

Acute Pancreatitis.—Transudation through the apparently intact walls of the pseudocyst was responsible for the diffuse peritonitis in the multipara, aged 29. She recovered after drainage of the cavity and clearing 200 cholesterol calculi out of the gallbladder.

A Case of Ovarian Cancer in Full Term Pregnancy. R. L. Rochat.—p. 787.
Physicians and the Legislation on Alcohol. A. Koller.—p. 788.

Metabolism Under Reduced Atmospheric Pressure.—Ehrlich presented convincing experimental evidence for the theory that arsenic compounds are toxic for the animal organism only when the arsenic is in the trivalent state. On the basis of this theory, Jaquet took the minimal lethal dose of pentavalent arsenicals (atoxyl and sodium cacodylate) as a means to measure the reduction processes in the rabbit under various atmospheric pressures. He found that under a pressure which is equal to an altitude of 1,800 meters, the lethal dose of these arsenicals is reduced by 22-23 per cent. as compared to the lethal dose under 760 mm. pressure. This demonstrates that even at an altitude which usually does not produce any subjective symptoms, the metabolic processes are altered.

*The Combined Sugar in Diabetes. V. Bisceglie.—p. 215.
*Syphilis of the Stomach. Luigi Ajello.—p. 227.
Experimental Lead Poisoning. Luigi Scremin.—p. 244.
*Chronic Infectious Endocarditis. A. Ceresoli.—p. 256.

The Combined Sugar in Diabetes.—Bisceglie reports experiences which confirm that the absolute and proportional amounts of the combined sugar in relation to the free sugar in the blood are doubled in diabetes. This is even more pronounced under the influence of insulin; as the free sugar drops, the relative amount of combined sugar increases. The hypoglycemia from insulin may be due in part to the transformation of the free sugar into the combined form.

Syphilis of the Stomach.—Ajello analyzes the necropsy records in the literature, classifying under seven headings the manifestations of syphilis in the stomach. A case described in detail presented a nodular sclerogummatous infiltration.

Chronic Infectious Endocarditis.—Ceresoli adds nine new cases of endocarditis lenta to the sixty already published in Italy. He confirms the etiologic importance of *Streptococcus viridans*, and the well defined clinical and histologic findings of this morbid entity.

Policlinico, Rome

*Membrane-Filtered Serums. E. Trenti.—p. 867.
Primary Cancer of Liver in Boy. C. Arrigoni.—p. 873.
Curetting the Uterus. N. Federici.—p. 876.

Biologic Reaction of Serums Filtered Through Collodion.—Trenti accepted the nonpassage of globulin through the collodion sac under pressure (60 cm. of mercury) as a reliable gage of the permeability of the sac. The filtrate of a serum that previously agglutinated typhoid bacilli and the melitensis had not a trace of agglutinating power left. The Wassermann and the Sachs-Georgi reactions were always negative in the filtered serum (twenty syphilitics; ten controls), but the reaction occurred with great intensity when the residuum was diluted, even with distilled water which must have upset the colloid balance.

*Intracardiac Injection of Epinephrin. F. Speciale.—p. 1149.
U. Biffi the Pioneer in the Sedimentation Test (1904). L. Lattes.—p. 1151.

Intracardiac Injection.—Speciale introduces the needle 2 cm. from the margin of the sternum, and perpendicularly, grazing the upper margin of the fifth rib. In a clinical case with prompt recovery from chloroform syncope after injection of 2 mg. of epinephrin, and in ten cadavers the needle entered the left ventricle. This allows the injected drug to pass directly to the central nervous system without the delay of passing through the minor circulation first. By this means the faintest throb of the heart is utilized for action on the respiration centers, as well as on the heart itself.

*Pneumothorax Treatment of Bronchitis. A. De Martini.—p. 697.
*Early Syphilitic Meningitis. Guido Milani.—p. 701.
*Malaria. M Battaglia.—p. 705.
*Colloidal Extracts of Tubercle Bacilli. A Grimberg.—p. 706.

Bilateral Pneumothorax in Treatment of Chronic Catarrhal Bronchitis.—De Martini reasons that an artificial pneumothorax would tend to immobilize the inflamed walls of the bronchi and give them a chance to heal. The sputum dropped from 200 to 60 c.c. in five weeks in one man. From 85 to 201 c.c. of the gas were introduced into the pleura on each side at each sitting as a rule. The intervals were from days to a week, and this pneumothorax treatment was kept up for five months, the sputum then 50 c.c.

Syphilitic Meningitis.—A recently infected young woman developed acute and severe syphilitic leptomeningitis. She recovered promptly under specific treatment except that the strabismus persisted for a few months.

Unusual Manifestations of Malaria.—Battaglia has had cases in which the absence of choked disk was the only puzzling element of a supposed brain tumor syndrome. In other cases the malaria induced intermittent psychopathies and cerebellar disturbances, the gait so altered that drunkenness was often assumed. Cases like these may develop insidiously, with little or no fever at first. Neuropathic disturbances of malarial origin are exceptionally tenacious. One of his patients presented all the symptoms of a sudden cerebral hemorrhage except that there was no conjugate deviation of the eyes. One malaria patient presented aphasia with right hemiplegia, as the fever ran high in an attack. Both in acute and in chronic malaria, changes in the walls of the vessels are common, up to diffuse arteriosclerosis. Aneurysm, on the other hand, he never found in malaria cadavers, probably because the blood pressure is generally low in malaria.

Treatment of External Tuberculosis.—Grimberg reports an additional series of 225 cases in which treatment was with his colloidal suspension of tubercle bacilli particles, triturated with iron filings in a magnetic field.

Tuberculous Pericarditis with Cirrhosis of the Liver. G. Griffo.—p. 546.
Increase in Guanidin Bases in Tetany. E. Pirami.—p. 555.

Epidemic Meningitis in Children.—Baldazzi summarizes eighty-five cases. The mortality was 47.36 per cent. among the nineteen given merely symptomatic treatment, and 55·32 per cent. of sixty-five treated with antiserum.

Basal Metabolism in Infants.—Bosio's figures obtained from fifty infants are very close to Benedict and Talbot's figures, with a tendency to higher figures and greater fluctuations in the malnourished. His figures (Du Bois' height-weight formula) were always higher than those obtained by the Pirquet formula.

*Treatment of Chorea. J. de Cardenas y Pastor.—p. 161.
Two Cases of Monosymptomatic Glomerular Nephritis, J. Gonzalez Edo. —p. 178.

Treatment of Chorea.—Keeping the child in bed is regarded as an essential element in the treatment of chorea by de Cardenas. He has found hexamethylenamin by the vein useful in epidemic encephalitis, and consequently gave it a trial in eleven cases of tenacious chorea in children, aged 6 to 12. Improvement was evident by the third injection, and one was cured with five in eleven days. In one child eighteen injections were made in six weeks, increasing from the usual dose of 2 c.c. of a 5 per cent. solution to 6 c.c. Typhoid developed a week later and proved fatal within a month. This case disproves the alleged prophylactic action of hexamethylenamin in respect to typhoid. In a more recent series of two cases of chorea he used a 10 per cent. solution with good results.

Perforation of Side-to-Side Entero-Anastomosis. E. Cornejo Saravia.—p. 137.
*Hydatid Cyst in Muscle. C. Velasco Suárez.—p. 139.
Spontaneous Rupture of Epigastric Artery. R. Donovan.—p. 142.

Arteriovenous Aneurysm at the Elbow.—The aneurysm had developed after the man had cut himself accidentally just above the bend of the elbow. Corachan did not extirpate the aneurysmal sac, but resected the artery, with an end-to-end suture. The illustrations show the technic and the apparently complete cure of all disturbances to date (four months).

Hydatid Cyst in the Abdominal Rectus Muscle.—Velasco Suárez has been able to find records of only four cases of a hydatid cyst in muscle tissue, and adds a fifth to the list. It had evidently started in the muscle but had developed inward toward the posterior sheath of the muscle, simulating an ovarian cyst.

Revista Médica del Rosario

Apparently Normal Pregnancy and Delivery with Cancer of the Uterine Cervix. P. Ferrazini.—p. 67.
*Trachoma in Rosario. C. Weskamp.—p. 80.
*Liver Function Test in Pregnancy. J. Watson.—p. 85.
Comparison of the Phenolsulphonephthalein Test and the Ambard Index of Urea Excretion. C. Alvarez.—p. 96.

Trachoma in Argentina.—Weskamp relates that 8.7 per cent. had trachoma of the 4,500 eye patients treated at the Hospital Español at Rosario, in the state of Sante Fé, during the years 1921 to 1923. At Buenos Aires the proportion averaged only 4 per cent., while in 1910 the same observer (Demaria) found 10.3 per cent. trachomatous. At Rosario 48 per cent. of those affected had been born in Argentina.

Liver Function Test in the Pregnant.—Watson applied to eleven pregnant women Rosenthal's phenoltetrachlorphthalein test. The response indicated that the liver function was below par after the fifth or sixth month. His impression is favorable to the use of this test to distinguish between a neurotic and a toxic origin for the vomiting of pregnancy, as suggested by Krebs and Dieckmann.

Revista Mexicana de Biologia, Mexico City

5: 361-386 (July) 1925

Syphilitic Origin of Unilateral Dystrophia. Pittaluga.—p. 361.

Different Types of Histologic Structure in the Nervous System. I. Ochoterena.—p. 374.
Clinical Study of Ascarids. E. Pous Cházaro.—p. 382.

The Sclera Implanted on the Capsule of Tenon.—Alonso clears out the sclerotic coat in enucleating the eye, drawing it inside out like a glove finger, and removing every trace of the uvea. The sclera is rinsed with physiologic solution and is then restored to its normal position inside the capsule of Tenon, to which it is fastened with U sutures and not merely at the edges. The illustrations of the three cases in which he has applied this method sustain his statements that the use of the artificial eye will appear much more natural with this technic.

Revista de la Soc. de Med. Interna, Buenos Aires

6: 73-175 (June) 1925

Ayerza's Disease: the "Black Cardiacs." L. Ayerza.—p. 73.

*Insulin in Treatment of Hyperthyroidism. F. Puchulu.—p. 140.
*Treatment of Tuberculous Diabetics. Roque A. Izzo.—p. 164.

Radiotherapy of Asthma.—The spleen was irradiated with half the skin dose of penetrating roentgen rays, and 46 per cent. of the twenty-six patients were completely cured: 38 per cent. much improved, and no benefit was apparent in 8 per cent. Two of the patients had such severe attacks of the asthma the day after the first irradiation that they refused to continue the treatment. The asthma was of long standing, from fifteen to twenty-five years in seven and for more than eight years in five, all in the group of complete cures after from one to three exposures. There has been no return of the asthma in the six to fourteen months since. In one case the chest was exposed in addition to the spleen.

Insulin in Treatment of Hyperthyroidism.—Puchulu states that treatment with 5 or 10 units of insulin had a favorable influence on the general condition; the weight increased and the patients became more tranquil, but the vegetative functions, the pulse, the systolic blood pressure, the glycemia, basal metabolism and menstruation did not seem to be influenced by the insulin. In the discussion, Waldorp mentioned a case of exophthalmic goiter with material improvement under insulin treatment.

Insulin in Treatment of Tuberculous Diabetics.—No unfavorable influence on the pulmonary disease could be detected from the insulin in the twenty cases reported.

*Mechanism of Diuresis Induced by Novasurol. O. de Mello Campos.—p. 414.
Some Nematodes of Arthropods. Lauro Travassos.—p. 416.

Mechanism of the Diuretic Action of Novasurol.—De Mello Campos states that the drug seems to unlock the tissues in dropsy, and thus allow the passage of the excess of water into the blood. This preliminary hydremia precedes the diuresis and explains it. Surprising results have been obtained with novasurol sometimes in cases of dropsy in Libanio's service, all with both heart and kidney derangement. Hydrophilia of the tissues is the special indication for this drug; unfortunately it has the disadvantages of all mercurials for patients with anasarca.

Biologic Bases for Radiotherapy of Cancer. Brachetto-Brian.—p. 25.
*Cure of Tuberculoma of Iris Under Tuberculin. P. Satanowsky.—p. 29.
*Vaccines in Surgery. A. Galindez.—p. 32.

Radiology of the Respiratory Apparatus.—Viton discusses the interpretation of the roentgen-ray findings in different pathologic conditions in the bronchi, lungs, pleura and mediastinum, reproducing seventy-five typical roentgenograms.

Tuberculoma of the Iris Successfully Treated with Tuberculin.—Satanowsky ascribes to the tuberculin treatment the subsidence of a tuberculoma of the iris in a woman of 33. Extremely minute doses were given, twice a week, for a period of five months. In a case of tuberculous iridocyclitis there was a febrile reaction to a dose of tuberculin representing 0.1 c.c. of the twenty zero dilution of the tuberculin, but the first patient bore this amount without a general reaction, and recovered under progressive treatment, gaining 3 kg. in weight while continuing at work throughout.

Vaccines in Surgery.—Galindez' experience in 100 cases confirms the advantages of preliminary injection of a polyvalent vaccine before operations. He injects 1 c.c. of the vaccine three days before the operation and 2 c.c. the day before. During the year since this has been his practice he has had no instance of pulmonary complications—an unprecedented freedom from postoperative mishaps. His list includes sixty abdominal operations and others for mastitis, leg ulcers, etc, and ambulant affections.

*The Blood Proteins After Operation. H. Hueck—p. 774.
Cardiospasm in Cancer of the Cardia. J. Palugyay.—p. 795.

The Hemostatic Effect of Blood Transfusions.—Determination of the coagulation and bleeding time does not yield a satisfactory explanation of the mechanism of hemostasis; but estimation of the thrombin and fibrinogen shows why blood transfusion has a tendency to arrest hemorrhage. This action is observed only if the transfused blood contains thrombin, and if the recipient's blood is deficient in thrombin. The amount of fibrinogen present does not seem to play any appreciable rôle in human pathology. Wildegans reports ten cases in seven of which transfusion had an immediate hemostatic effect; in two cases the effect was only of short duration, and in one case (bleeding from a larger branch of the hepatic vein) no success was obtained.

Hernias in the Semilunar Line.—Koljubakin reports eight cases of these hernias. He found that the protrusions usually occur where the blood vessels pierce the aponeurosis of the transverse abdominal muscle. In the same locations, subperitoneal lipomas are not infrequently found, which may play an important rôle in the pathogenesis of these hernias.

Calcium in Blood and Pus.—Schulze and Scheller found that the blood has regularly a high calcium content in all suppurating diseases, not merely in those cases in which bones are affected. The same is true for the pus. The authors believe that this is one manifestation of the reaction of the organism against the inflammatory process, and that the frequently observed atrophy of the bone in such conditions is caused by a decalcification in order to put the calcium at the wider disposal of the body. The process of final calcification in certain scar formations, consequently, is not a secondary process but one which starts with the very beginning of the inflammation.

Blood Proteins After Operations.—Hueck observed as a general rule that in the postoperative period the blood fibrinogen and the rate of erythrocyte sedimentation are increased, but not necessarily proportionately. The total proteins and the ratio of albumin to globulin are decreased. The surface tension of the serum is not uniformly changed.

Thrombopenic Purpura.—Leschke introduces various clinical and experimental evidence for the theory that the decrease of thrombocytes cannot explain satisfactorily the pathogenesis of this disease, but that a simultaneous pathologic condition of the capillary endothelium is a coordinated factor. The bleeding time does not always parallel the thrombopenia.

Photomicrography on the Living Brain.—Jacoby and Magnus describe a method by which it is possible to make microscopic studies and to take photomicrograms on the living brain. This method has been applied especially to the study of blood and lymph circulation.

Syphilitic Polyneuritis.—Koehler describes in detail two cases of this rare affection One of the cases was observed during the late secondary stage, the other in the tertiary stage.

Diphtheria of the Accessory Nasal Sinuses.—Sonnenschein found that diphtheria bacilli not infrequently cause purulent inflammations of the sinuses A complete cure may be obtained by antitoxin and vaccine treatment, and surgical interference is not necessary

Treatment of Peptic Ulcers.—Friedemann advocates in severe cases of peptic ulcers a radical operation, namely the removal of that part of the stomach or duodenum which contains the ulcer, including the pylorus and antrum, and to close the stomach by the Billroth I or II method. He found that such radical resections influence the chemistry of the stomach very favorably, and give good and permanent results. In 536 operations he had a mortality of 5 5 per cent. as compared with 14.4 per cent. in nonradical operations; 94.2 per cent. of the patients were free from symptoms after three years, as compared to 68.4 per cent. of the gastroenterostomy patients.

The Blood Platelets in Surgical Maladies.—Hueck concludes from counts of the platelets in 100 cases that this method does not play a significant rôle in surgical diagnosis. In the first five days after operation a decrease is usually found; then a rise is noticed beyond the normal by the eighth to the eleventh day, and after this a slow return to normal values.

*Bone Formation in Dura Endotheliomas. A Weiser.—p. 405

The Value of Intraspinal Anesthesia.—In five hundred cases of spinal anesthesia only 1 per cent of failures was observed, and not a single serious ill effect. Grumach emphasizes the importance of proper technic and indications.

Xanthomatous Giant Cell Tumors.—Wustmann believes that these pathologic products are not true tumors, and certainly not true sarcomas. They are formed to accumulate the excess of cholesterol in these patients. Xanthomatous new growths are strictly dependent on the cholesterol diathesis. They practically never metastasize, and their growth is not infiltrative and destructive.

Bone Formation in Endotheliomas of the Dura.—It is well known that in a considerable percentage of endotheliomas, hyperostoses of the skull are found opposite the tumor. Weiser reports two cases where he found true bone formation on the cerebral surface of endotheliomas. He believes that this occurrence has never been described in the literature before.

Decreased Meningeal Permeability in Schizophrenia.—Hauptmann examined the meningeal permeability in different psychopathic patients, using as test object bromin. Out of twenty-four patients with schizophrenia, seventeen showed a considerable decrease of permeability; in six the values were within the normal range, and one had an increased value. The author believes that this decreased permeability, which he never found in patients with manic-depressive insanity, indicates a disturbance in the nourishment supply of the central nervous system.

Induced Decrease of Gastric Secretion.—Glaessner found that fever, artificially induced by injections of nuclein and similar substances, does not noticeably affect the gastric secretion. Certain vaccines, however, especially typhoid vaccine and tuberculin, decrease the amount of the gastric secretion, its hydrochloric acid and pepsin considerably, and over a period of several weeks.

Glycolysis of Vaginal Tissue.—Loeser examined on explanted vaginal mucosa the glycolytic action of this tissue, using the method that Warburg evolved in his well known cancer studies. He found that living vaginal mucosa splits glucose into lactic acid, and that this process is the more active the healthier and constitutionally stronger the individual from which the excision was made.

Hemo-Opsonins.—Serum substances which stimulate phagocytosis of the erythrocytes of the same species were first demonstrated by Hektoen. Schiff studied these "isohemo-opsonins" in their relation to the iso-agglutinins, and found that they are divided into the same four blood groups. Their occurrence is not far as frequent as that of the agglutinins, but whenever they are present in a serum they always act exclusively on the same groups of red cells as do the agglutinins of this serum.

*Twins with Congenital Syphilis. O. Herz.—p. 467.

Subcutaneous Vaccination.—The subcutaneous injection of a dilution of 1:200 of vaccine produces the same immunity as cutaneous vaccination; the incubation period is the same in both methods, and it is a few days longer in intracutaneous vaccination. Kuhle advocates the subcutaneous technic in cases where scar formation must be avoided, and when vaccination is imperative in patients with skin diseases.

Avitaminosis in Breast-Fed Children.—Petényi believes that breast-fed children may develop avitaminotic conditions, such as retardation of development in general and mild forms of anemia. This is due to the deficiency of the vitamin D in the milk. The addition of a small amount of vegetable to the food is very effective.

The Cytology of the Bone Marrow in Infants.—Smears from the bone marrow show on an average 61 per cent. of myeloid cells and 25 per cent. lymphocytes; the former group consists of promyelocytes, myelocytes and leukocytes, predominantly young types. Less than 1 per cent. basophil leukocytes, and 1-3 per cent. eosinophil leukocytes are found. There are about 5-10 nucleated red cells to each hundred white cells; but in syphilis and rickets their number is much increased (to 47 per cent. and 20 per cent., respectively). In infants with exudative diathesis one finds frequently a considerable eosinophilia (8-9 per cent.) even if the blood eosinophils are not increased in number. Rickets and whooping cough induce lymphocytosis in the bone marrow. Kramár and Hensch believe that diagnostic puncture of the bone marrow does not involve any danger, if done properly.

Congenital Syphilis in Nonidentical Twins.—Herz reports the history of a girl 3 weeks of age with the typical symptoms of congenital syphilis and a four plus Wassermann reaction. She died seven days after admission to the hospital. Her twin brother died more than three months later of bronchopneumonia and empyema. He never showed any symptoms of syphilis, his Wassermann was always negative; the necropsy and the histologic examinations did not reveal any signs of syphilis.

Antibodies After Tuberculin Administration. — Gruschka and Guth found that the injection of tuberculin in small amounts is followed by the production of complement fixing antibodies in active tuberculous patients. Nontuberculous persons do not develop these antibodies even after considerable amounts of old tuberculin.

Pulmonary Tuberculosis in the Jew.—Werner analyzed the course of the disease in 225 patients. He found that the disease tended to severer forms in the postwar period (in Berlin) than before the war; but still he believes that, compared with other statistics, pulmonary tuberculosis takes a milder course in the Jewish patient than in the Gentile.

Periarterial Sympathectomy.—Monaschkin made histologic studies on three patients who had been operated on on account of spontaneous gangrene. The fact that the vasa vasorum are removed or severed by the operation may entail necrosis of the arterial wall. The operation may lead to a sclerotic scar which constricts the artery. It is therefore important to surround the decorticated artery with fat tissue

Immunization Against Cancer. — Waterman's further research has confirmed his assertions last year in regard to a heat-stable substance in the extracts of benign tumor filtrates which activates glycolysis without having a direct ferment action itself. It proved possible by preliminary treatment with extracts of benign tumors to make mice refractory to inoculation of malignant tumor substance. It is not a true immunizing process, but merely a modification of the hormonal system, as is evident in the changes in the sugar content of the blood and in glycolysis. A similar inhibiting influence is apparent also with injection of insulin. He urges that this nonspecific inoculation should be applied as an adjuvant in treatment of human cancers, especially in prophylaxis of recurrence.

Thrombosis of Mesenteric Veins. — Michael operated promptly, removing 3 meters of the small intestine with the edematous mesentery and thrombosed vessels The sudden intense pain around the navel, with paroxysmal recurrence, had been preceded by a month of occasional vomiting, and anemia, with hemoglobin 38 per cent. A month after the operation the spleen enlarged and thrombosis became evident in the femoral vein, but this all subsided harmlessly, and the young woman left the hospital in good condition. A miscarriage four months before may have been responsible for the whole process.

Enlargement of the Thyroid in Art.—Ten reproductions are given of paintings of Madonnas by the old Dutch, German or Italian masters, and van Leersum gives a list of others in all of which the neck shows more or less thyroid enlargement. He calls attention further to the prominent Adam's

He remarks that some of them would not be out of place in a textbook on pathology. He adds that the extremely high forehead or long fingers in certain works of art may be regarded as simply a question of the artist's taste, but the number of paintings from the fifteenth and sixteenth centuries showing enlargement of the thyroid testifies that this was common in that age. This demonstrates that the incidence of goiter cannot be explained by any factor which has come into play only in the last century or two.

*Examination of the Blood. W. Schüffner and Ruys.—p. 710.
*The Concentration Trend in Evolution. W. A. Mijsberg.—p. 719.

Minor Points in Examination of the Blood.—Schüffner and Ruys point out that the leukocytes retain their shape if the specimen of blood is allowed to dry slowly, of itself, without waving in the air. They also warn that there is a peripheral monocytosis which may prove misleading. The count in blood from the ear varies widely according as the ear is pale and cool or has been well reddened by friction.

Concentration as a Phenomenon of Evolution.—Mijsberg carries still farther Bronn's conception of the seven evolutionary processes, culmination, differentiation, concentration, centralization, interning of the vital organs, and increase in the size of the body, with reduction in the number of similar organs. He illustrates his views in particular with the comparative anatomy of the vascular system, the evolution from the multiple and scattered to the simple and concentrated.

Daily Blood Sugar Variations in Diabetics. A. Flaum.—p. 372.

Essential Thrombopenia.—Höglund recapitulates all the various theories on the pathogenesis of this disease, and gives a complete survey of the literature on the subject. He reports three cases of his own *in extenso*, and formulates the indications for the treatment as follows: In mild cases, conservative treatment and the administration of hemostyptics should be tried first. If no improvement is obtained, roentgen-ray treatment of the spleen should be given. In severe cases, or when any other treatment proves unsuccessful, removal of the spleen is indicated, and this achieves usually a prompt arrest of the hemorrhagic diathesis.

Two Cases of Broncho-Esophageal Fistula.—Westergren and Ragnell found in one case a fistula connecting the esophagus with the two main bronchi, which was formed by the breaking down of a tuberculous mediastinal lymph gland. In the other case, an esophageal diverticulum had perforated into the right lower lobe, where extensive gangrenous processes were found.

Passage of a Stain into the Cerebrospinal Fluid.—Jervell tabulates the details of seventy-six cases in which the lumbar puncture fluid was examined after ingestion of uranin. If the fluid does not show the stain three hours after 2 gm. of uranin has been taken by the mouth or injected intramuscularly in a 20 per cent. solution, then meningitis can be excluded. A pronounced change of tint indicates extensive meningitis but not its form. Uranin does not pass into the saliva, tears or other secretions but stains the tissues readily and passes into exudates. This suggests that the spinal fluid in meningitis is more of the nature of an exudate than a secretion. No trace of the stain in the spinal fluid was left by the eighteenth hour. He adds that it might be interesting to determine whether intravenous injection of solutions of various other substances in different concentrations might modify the permeability of the meninges for the stain, and thus for drugs.

Coxa Plana.—Widerøe gives a three-year series of roentgenograms of a case of the Calvé-Legg-Perthes hip joint affection. They show clearly a phase of destruction for about a year and a half, and then two years of reconstruction.

Pituitary Tumor Improved by Pituitary Treatment.—Amenorrhea in 1918 and progressive impairment of vision in 1921 were soon followed by an epileptiform attack once a month, with loss of consciousness. The woman had three healthy children. In 1923 the sella turcica and the urine seemed to be still normal. Treatment was then begun with potassium iodid and thyroid and pituitary extracts. Menstruation promptly returned and there were no further epileptiform seizures. The single seizure each month seemed to be a kind of vicarious menstrual manifestation, and the return of the menses twenty-four hours after the first dose of pituitary extract seems to indicate some toxic connection between the pituitary and the menstrual process. During the two years since 1923 the woman has had a few very mild returns of the seizures and two severe ones. Radiotherapy for the assumed pituitary tumor was contemplated but not attempted.

Rupture After Cesarean Section.—Schaanning compares the literature with his own experience in 88 cases of cesarean section since 1908. There was no instance of rupture or other complication of childbirth later in the group of 28 vaginal cesarean sections or in the 18 cervical, but there was one case of rupture in the 42 classic corpus cases. Only 39 of the total 88 have been known to pass through a pregnancy since, but some have borne up to three children.

PITUITARY DISORDER

A DIGEST OF ONE HUNDRED CASES, WITH REMARKS ON THE SURGICAL TREATMENT *

CHARLES H. FRAZIER, M.D., Sc.D.
AND
FRANCIS C. GRANT, M.D.
PHILADELPHIA

The first operation in the neurosurgical clinic of the University Hospital for the relief of a symptom or effect of primary pituitary disease was performed in 1912, and since that time 175 patients have been added to our pituitary register. While surgery is recognized as a factor in the care of the patient with pituitary disorder, yet there is a certain amount of hesitation or uncertainty on the part of physicians as to what advice to give such patients. It is only proper that a fair statement should be made as to what may be accomplished by such methods of treatment as are available; to wit, glandular therapy, radiotherapy and operation.

TREATMENT

I can pass over the merits of glandular therapy, as my experience has been entirely barren of results and this applies only to patients who have already developed pressure symptoms. Obviously, such patients as may have responded to glandular feeding would not have been referred to the neurosurgical clinic. I have no doubt that an occasional case, depending on the nature of the lesion, responds to the administration of pituitary extract with or without thyroid extract; but, judging from what records are available in literature, the success of glandular therapy in relieving the pressure phenomena of pituitary lesions must be the exception rather than the rule. However, even with this trivial chance of betterment, the patient should be given the benefit of the doubt; and, assuming that vision is not threatened, a course of treatment with glandular extracts is quite within the bounds of propriety. Be it said at this time, and this applies to all methods of treatment, that we have in the intensity of headache and in the measurements of the pituitary fossa, but more particularly in the examination of the eyegrounds and in the perimetric studies, a trio of indexes that give indisputable evidence of the progress of the case. With the roentgenologist and the ophthalmologist for consulting service, one can rest assured that information will be available as to whether the lesion is progressing, stationary, or in process of retrogression.

Because the pathologic condition in pituitary lesions is fairly constant, the majority being adenomas, and because the location of the lesion can be determined with great precision, the roentgenologist is supplied with information of great value in determining dosage and other technical details. Despite these apparent advantages, I am inclined to believe that roentgen-ray therapy has been employed to a limited degree in this country and that the percentage of positive results is small. In my own series there were only three cases in which unquestionably the lesions were favorably affected by irradiation, and whether in these the results will be permanent or only transitory is still an open question. However, as with organotherapy so with irradiation: in incipient cases these nonsurgical measures with propriety may first be given a trial. Naturally if the lesion is, as in many cases, a cyst, or if, as in a still larger percentage of cases, the adenoma has undergone cystic degeneration, the effect of irradiation would be nil.

Finally, there remains, as the court of last resort, if you will, surgical therapy. Deferring for the time being all matters relating to the operative technic, three leading questions suggest themselves. 1. When does the case of pituitary disorder become a surgical problem? 2. What may be accomplished by operative procedures? 3. What are the immediate and end results?

1. Since, as a rule, we are not confronted with symptoms that threaten life, an operation in pituitary lesions is one of choice, not one of necessity. It is optional with the patient whether, in the face of inevitable blindness, forecast by the advancing optic atrophy, when headaches are unbearable and when the disability and disfigurement of an acromegaly become encumbrances, he shall submit to an operation for their relief. It is only proper at this time to inject a warning as to the dangers of procrastination. The more advanced the optic atrophy, the more advanced the acromegaly and the longer the duration of the lesion and its effect on other endocrine glands, the less surgical intervention can accomplish. Too frequently the surgeon is confronted with end-results of the disease, and with terminal states when relief is out of the question.

2. At one time we were wont to think that the effect of operation was only that of relieving pressure phenomena, the visual disturbances and headache; but it has become evident that the clinical evidence of functional disturbance, whether it be in the form of acromegaly or the Frölich syndrome, may be favorably influenced. Cases might be cited in which the patient was relieved of somnolence, in which fatigability had given way to normal vigor, in which there was diminution in the size of hands and feet, and loss of weight in those with great accession of fat. These possibilities at once suggest a much larger scope for surgical treatment than was at one time reckoned with; but in practice we find the patient unwilling or unprepared, perhaps because uninformed, to consider an operation until vision is seriously impaired, if not altogether

---

* Read before the Section on Nervous and Mental Diseases at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

threatened. This has been our experience with the exception of a small series of cases, five, in which severe headache was the predominant indication.

Physicians still look askance at surgery as a means of relief, when confronted with a patient with pituitary disorder, and this, perhaps, is what one might expect when the issues at stake have not been clearly set forth. Consequently, the question of operation has not been faced until the situation has become desperate and the surgeon has been confronted for the most part with the terminal effects of the disease, with advanced optic atrophy and with late stages of the various functional disorders, dwarfs or full blown acromegalic patients; and in evaluating the results of the surgeon's attempt to restore the patient to health, these facts must be given due consideration.

3. The facts which should be clearly set forth are those which have to do with the immediate results, or operative mortality and the end-results. The operative mortality depends on whether the lesion is approached by the nasal or by the intracranial route. In the last twenty-nine operations, performed since October, 1919, there has been but one fatality, a mortality of 3.4 per cent. Prior to that time, when the technic of the operation had not been perfected as it has today, the mortality was higher. Altogether there have been six deaths in our entire transsphenoidal series. As our experience grows, and further refinements in the technic suggest themselves, this mortality of 3.4 per cent. will, we believe, be still further reduced. (It is not so very long ago that the mortality of the major operation for trigeminal neuralgia, now less than 0.5 per cent., was 5 per cent. and over.)

In the neurosurgical clinic of the University Hospital it is now our practice to perform the transnasal in preference to the transcranial operation in every case in which there is no reasonable doubt that the lesion is in great part within the confines of the sella turcica. In this choice of operative approach, our selection has been influenced in part, but in large measure, by the fact that the mortality of the transnasal operation is decidedly lower than that of the transfrontal operation; and until the time comes when by the transfrontal approach we are able, without a prohibitive mortality, to deal radically with the pituitary lesion, and by that we imply a complete evacuation of the sella contents, we shall continue our present practice with such limitations as it involves.

The mortality of the transfrontal operation for primary pituitary lesions has been acknowledgedly high, 30 per cent. In other clinics a mortality rate of 40 per cent. and over has been recorded. The crux of the situation is this: The transfrontal approach unquestionably gives the better exposure and the only one that permits a complete extirpation of the lesion, which implies a complete evacuation of the sella contents. This is, as we know, a difficult and hazardous procedure. When we are able to accomplish this with a risk proportionate to the gravity of the situation, the tide will turn, and the transfrontal approach will be the accepted procedure. We must remember in the consideration of these technical problems that in possibly eight out of ten cases the lesion is an adenoma, fairly uniform in its physical proportions. If our practice is limited to a subcapsular enucleation of the adenomatous contents, whether by the transnasal or transfrontal approach, for the present at least preference should be given to the operation that involves the least risk.

In 1923 I[1] reviewed the effect on vision in the series operated on in the years 1919-1923, and the results at that time were expressed as follows: striking improvement in 35 per cent., moderate improvement in 35 per cent. and stationary or aggravated in 27 per cent. In other words, there was an enlargement of the field and better vision in one or both eyes in 70 per cent. In the series operated on since then, the percentage of improvement has been sustained. In only one case was there no improvement following operation. In the series of 100 cases we have records of six deaths after discharge from the hospital, two after three, six and twelve months, respectively. Three patients in the series died from meningitis, one before operation and two after discharge from the hospital. Of the total operative series, in 22 per cent. there was evidence of improvement in the glandular symptoms soon after operation.

ANALYSIS OF CLINICAL MANIFESTATIONS IN THE AUTHOR'S SERIES OF ONE HUNDRED CASES

Classification.—For convenience of study, cases with pituitary lesions may be divided into four groups:

1. Pituitary dysfunction, under this term including cases with manifest symptoms of pituitary dysfunction, but without enlargement of the pituitary fossa and without pressure phenomena. For the most part patients in this group will be found among adolescents and, not presenting any surgical indications, should be placed under the care of the endocrinologist. 2. Suprasellar lesions, as the term implies, referring to lesions primarily extrasellar, but with striking evidence of pituitary disorder, and often calling for surgical relief. 3. Pharyngeal pouch tumors, closely, to be sure, related to the pituitary gland disorders but with a different origin and presenting a different surgical problem. 4. Primary pituitary or primary intrasellar lesions, the group representing the majority of surgical indications in the pituitary clinic. In this analysis my remarks will be confined to the last group, comprising a series of 100 cases.

Etiology.—The predominance of males over females, in the proportion of 65 to 35, is mentioned although the significance of this is not apparent, and the prevalence in the third and fourth decades is conspicuous; 53 per cent. were almost equally divided between the third and fourth decades; 31 per cent. developed in the second and third decades. There was only one patient under 10 years of age; thirteen were over 50 years of age, and only four 60 years. These ages represent the time at which the patient presented himself at the clinic for treatment. If any conclusions are to be drawn from these statistics, one is that the great majority of pituitary lesions, as we see them in the clinic, appear between puberty and middle life; that is, in the period of greatest sex activity. As we know from experimental and clinical evidence, there is a not distant relationship between the sex glands and the pituitary body; but whether this relationship has any direct bearing on the etiology of pituitary lesions is, of course, hypothetic.

Duration of Lesion.—There is apparently a wide divergence in the time that elapsed between the appearance of the first symptom and the time in which the condition demanded relief. This might be said to be only an approximate index of the development of the lesion, as measured by time, since in some instances the patient reported to the clinic at a relatively early period; but the time varies from six months to twenty-nine years.

---

[1] Frazier, C. H.: Surgery of Pituitary Body, Arch. Surg. 8: 39 (Jan.) 1924.

Predisposing Causes.—The previous medical histories were analyzed with a view to determining the prevalence of any predisposing cause, and in this connection it is interesting to note that in 11 per cent. there was in the family history a record of some endocrine disturbance. The question has arisen at times as to the relationship of cranial trauma to pituitary lesions, especially basal fractures through the pituitary fossa, but in only 6 per cent. was there an injury to the head recorded in the history, and in not all of these cases was the injury of any serious moment. Certainly the percentage is not high enough to carry with it any etiologic significance. Excluding endocrine antecedence and cranial trauma, we have nothing but a medley of diseases in the previous history, the exanthems and the more common infectious diseases, no one of which was recorded in more than 8 per cent. of the series. The relationship between syphilis and pituitary disease has been a subject for discussion, but so far as being able to demonstrate conclusively that the lesion was definitely syphilitic, there is not a single one of our series that could be so catalogued. In five instances, because of positive serologic reactions, antisyphilitic remedies were incorporated in the postoperative treatment; but that these had any definite influence on the course of the disease, we have no testimony to offer.

By way of parenthesis, a word should be said as to the acceptance of statistics on pituitary lesions that emanate from a neurosurgical clinic. What may apply to surgical lesions of the pituitary gland, if we may so qualify those with pressure symptoms, might not apply to all pituitary lesions without qualification.

Initial Symptoms—In our series of 100 cases, the initial symptom, according to the patient's statement, was failing vision in 71 per cent. and a later development in 16 per cent. Thus, in 87 per cent. of our patients, failing vision was probably the outstanding indication for treatment. That the initial symptom should have been failing vision in more than three fourths of our patients deserves passing comment That the lesion should be large enough, and therefore of months' if not years' duration, to cause pressure on the optic tracts or chiasm without previously having provoked any noticeable evidence of pituitary dysfunction is at least surprising.

In 27 per cent. headache was the initial symptom and a later symptom in 61 per cent ; it was described as severe in 37 per cent., as moderate in 15 per cent and as slight in 9 per cent. "Pituitary headache," as we understand the term, implies tension within the pituitary capsule, and one would rather expect a more or less constant location to which the pain is referred As a matter of fact, in our series the location was varied and was described as frontal (seventeen), frontooccipital (five), frontotemporal (seven), vertexfrontal (one), occipital (five), vertexoccipital (two), occipitotemporal (three), temporal (three) and general (seven). Thus the majority in this series were frontal, followed in order of frequency by occipital, general and bitemporal. While headache was recorded as severe in one third of the total number of cases, as a matter of fact in only five cases was it the outstanding symptom for which the patient sought relief.

Ocular Phenomena.—The ocular phenomena of pituitary disease would take us too far afield. The field defects and optic atrophy are, of course, the prevailing findings, and a brief statement as to these may be made. What may be accomplished by operation in restoring vision obviously depends on the presence and degree of atrophy, and as an evidence of the unfortunate delay in seeking operation we find optic atrophy recorded in 41 per cent. and in more than half of these there was total or almost complete blindness in one eye, with deterioration of vision in the other. The yellowish discoloration of the disk, really pathognomic of pituitary disease, was recorded in 35 per cent. of the cases. The perimetric studies we will not go into here. That bitemporal hemianopia is by no means the universal field defect is now well known. The variability of the perimetric findings is probably due to the variable position of the chiasm with relation to the pituitary body, as shown by Schaeffer, and certain bizarre fields are the effect of pressure of the vessels of the circle of Willis, or of irregular protuberances from the surface of the adenomatous mass. An exceptional effect of an adenomatous protuberance on the lateral aspect of the tumor, as illustrated by one case in our series, was an oculomotor palsy. Suffice it to say, in conclusion, that perimetric studies are of importance not only as of diagnostic value, but also as the most reliable index of the progress of the disease.

Sellar Deformation.—The diagnosis of a primary intrasellar lesion is on the whole not difficult if, as is implied by that term, it is a lesion which in its growth has caused an alteration in the size and shape of the sella turcica. The interpretation of the roentgenogram is a matter of prime importance not only as a diagnostic essential, but also in the selection of the operation as a guide to the method of approach An attempt has been made to state in figures what may be accepted as the dimensions of a normal sella turcica. Whether it be 12 mm. anteroposterior by 10 mm. vertical, a millimeter or two more or less is not a vital matter, since by the time the lesion is large enough to give pressure symptoms, the dimensions of the sella turcica have exceeded the normal limits sufficiently to be recognized as abnormal. Furthermore, in many cases the atrophy of the posterior clinoid processes and the dorsum sellae preclude the possibility of making accurate anteroposterior measurements. The deformation of the sella turcica characteristic of a primary intrasellar lesion is the

increase in the vertical dimension, and the best guide as to this is the degree of encroachment of the sella on the sphenoid sinus. This observation can be readily made, and for a proper interpretation of the roentgen-ray shadow one need not depend on any measurement. Admitting an occasional exception, this method of interpreting the roentgenogram is the most dependable in distinguishing, as one must, between a primary pituitary lesion, essentially intrasellar, and a lesion superimposed, extrasellar, and a lesion not of pituitary origin. When the measurements were recorded in our series of 100 cases, in every case but one the measurements exceeded 12 mm. by 10 mm.; the highest anteroposterior diameter was 25 mm., and the highest vertical 22 mm. Between these and the so-called normal dimensions there were many variations.

CONCLUSIONS

The surgery of the pituitary body, as practiced today, has limitations, proportionate in large measure to the duration of the lesion. When surgery is recognized as an essential factor in the treatment of the pituitary lesion in the early stage, before optic atrophy is advanced and before the terminal stages of functional disorder are reached, there will be a decided improvement in the operative results and a lower mortality. The surgeon has been handicapped because he has been confronted so often with terminal effects.

3600 Walnut Street.

ABSTRACT OF DISCUSSION

Dr. William G. Spiller, Philadelphia: I should like to ask Dr. Frazier to make a little more definite statement as to what is the period of the growth of the tumor when he does urge operation, not merely when the patient is willing but when he recommends it. In a case in which there is very little endocrine trouble, and there are many cases of that kind, in which the visual fields are not greatly affected and the headache is not very intense, the patient hesitates often to have an operation, which he regards as serious. Therefore, I wish Dr. Frazier would tell us whether he recommends early operation in such a case as that. The transsphenoidal operation can hardly be regarded as a total extirpation of the tumor. It is a relief operation. It would be interesting to know from his experience to what extent symptoms have continued in his cases after a portion of the pituitary tumor has been removed in the transsphenoidal operation. His paper is devoted entirely to sella growths, but I think he will agree with me that often the clinical diagnosis between sella growths and suprasellar growths is extremely difficult, and that the destruction of the clinoid processes and the enlargement of the sella turcica may occur in both. I remember a case in which destruction of the clinoid processes and enlargement of the sella occurred with a tumor of the cerebellopontile angle.

Dr. Charles H. Frazier, Philadelphia: With regard to the ideal time at which an operation should be performed, I should say this: The first evidence of visual disturbance usually is a contraction of the temporal field; eventually both temporal fields will be lost; probably then a provisional diagnosis could be made and confirmed by roentgen-ray study. The patient then might receive a course of treatment in feeding by pituitary or thyroid extracts, one or both; he might receive a course of treatment by irradiation. He should report to the ophthalmologist at least once a month for perimetric studies. If despite the treatment prescribed the fields either remain stationary or become more contracted, and if there is a suggestion of beginning optic atrophy, this is the time, if the patient expects ever to be operated on, for the proposition to be submitted to him. He should be told at that time that, unless something is done to arrest the natural sequence of events, first, he will probably lose the sight of one eye, then of the other, and eventually become totally blind. Dr. Spiller's second question was as to the permanence of results. We all know that there is possibility of recurrence in these cases. Just exactly what that percentage is, I am unable to say. So far as my own experience goes, I have operated only once for recurrence; I do not mean to imply by that that there may not have been more recurrences, but I do know that but one patient has returned to us, seven years after the original operation, for a second operation because of recurrence. We have certain reasons for believing that, if after the operation the patient receives a course of roentgen-ray treatment under proper direction, there is less likelihood of recurrence than if this postoperative course of treatment is omitted. I think it would take us a little too far afield to go into a discussion of a differential diagnosis between suprasellar lesions and the primary intrasellar lesions. When we are confronted with an instance in which there is reasonable doubt as to whether it is a suprasellar or an intrasellar lesion, we almost invariably approach the lesion by the transfrontal route.

DETERMINATION OF LOCAL COMPRESSION AS AN INDICATION FOR LAMINECTOMY

IN ACUTE INJURY OF THE SPINAL CORD *

CLAUDE C. COLEMAN, M.D.
RICHMOND, VA.

It is generally accepted that the early clinical examination of a patient with a severe cord lesion is often inadequate to fix the extent of the injury. The most that can be said of many such cases is that there is a complete physiologic interruption of the cord. Whether the lesion is a recoverable one or permanent, and whether a partial lesion is being converted into a complete one by pressure are problems that may be solved by time, but rarely permit prompt decision. If the cord is not subjected to pressure, operation is not only futile but increases the damage to the spinal column already weakened by the injury.

In fracture dislocation of the spine, pressure on the cord may be caused by the displacement of fragments of the vertebrae or malalinement of the vertebral column at the site of displacement. Extradural or intramedullary collections of blood and edema with swelling of the cord in a normal dural canal may also result in local compression. Whatever the cause of the pressure, the result is a partial obstruction or a complete occlusion of the spinal subarachnoid space at the site of the injury. Obstruction of the spinal subarachnoid space following trauma may therefore be regarded as satis-

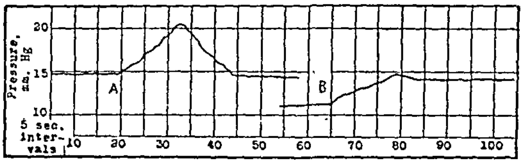

Fig. 1 (J. I. P., March 20, 1924).—Fracture dislocation of the sixth *cervical vertebra on the seventh, with comminution of the right side of* the body and lamina of the seventh. Operation showed swollen cord, with penetration of dura on right side by bone fragments. Apparently there was complete obliteration of the subarachnoid space. Marked improvement followed. Manometric tests sixteen hours after injury showed incomplete block; twenty-four hours later the block was complete, as shown by the second tracing at the right. *A*, jugular compression, March 20; *B*, jugular compression, March 21.

* Read before the Section on Surgery, General and Abdominal, at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

factory evidence of pressure on the cord. The uncertainty that usually prevails as to the local conditions about the injured segments of the cord has led to operations, which have shown the cord to be lying perfectly free in an undeformed canal, with no possibility of being benefited by laminectomy.

Roentgenograms cannot be depended on to give definite information of cord compression by small, in-driven fragments of bone. Certainly no help could be expected from roentgen-ray examination in the diagnosis of compression of a swollen cord by the dura, when there is no bony deformity.

Thompson,[1] in a careful review of the pathologic specimens in thirteen cases, concludes that recoil of the vertebrae after the displacing force has ceased to act is the general rule and that operation is rarely justified. Four of his specimens, however, showed a permanent narrowing of the bony canal, which by continuous pressure had converted the cord into a tapelike band. While it often happens that a fracture dislocation of the spine crushes the cord at the level of impact, it is also probable that partial lesions which might recover are made complete when the pressure is not relieved by prompt operation.

From the study of a series of fourteen patients, sufficient data have been obtained to justify the conclusion that the essential indication for operation in spinal cord trauma is the existence of a pressure on the cord, as determined by a block of the subarachnoid space. The adoption of a mechanical test for a mechanical condition at once clarifies much of the confusion resulting from the attempt to settle the operative indications on the basis of a complete or incomplete physiologic interruption. Either of these conditions may exist with or without the need for laminectomy, depending on whether the operation can remove something that is causing progressive cord destruction.

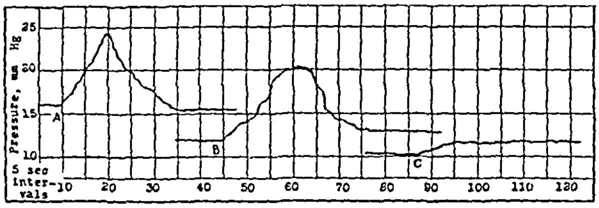

Fig 2 (C P T, June 6, 1924)—Fracture dislocation of seventh cervical, with comminution of laminae Small areas of tactile sensation retained in legs Lesion otherwise complete physiologically. Laminectomy *Death thirty hours later in hyperthermia Chart shows fluid* pressure curves of three manometric tests The first test, done on admission, showed no block The second, about fourteen hours later, showed a delayed rise with halting of the fluid column in its ascent. On jugular release, pressure does not fall promptly The block became complete twenty four hours later, as shown by tracing at right At this time, operation was done Jugular compressions. *A*, June 16, *B*, June 17, *C*, June 18

Interruption of the spinal subarachnoid space may be determined by roentgen-ray examination of the spine after the injection of lipiodol into the spinal canal, by double puncture or by lumbar puncture combined with jugular compression. Of these methods, Ayer's[2] double puncture or simple lumbar puncture with jugular compression is more satisfactory. Mixter,[3] in 1923, included the test for subarachnoid block among the methods of study which patients should receive to determine the indications for operation in cases of fracture dislocation of the spine with cord injury. In our group of cases, Ayer's double puncture was used on two patients. In twelve cases of this group, the question of pressure on the cord was decided by the Queckenstedt[4] test alone. It has been of some interest to note in two of our cases an increasing block, which became complete in from eighteen to forty-eight hours after injury (Figs 1 and 2).

Allen[5] found that cord edema experimentally produced reached a maximum in four hours and that after this period longitudinal section of the injured segments was of little benefit in preventing the harmful effects of the edema. This conclusion would seem to predicate cord destruction on a very early edema, which may be many hours ahead of the maximum cord swelling, as shown by the time of the appearance of a complete block in two of our cases. While the evidences of partial block as shown by the Queckenstedt test are of the greatest importance in the study of cord tumor, we have not considered anything short of an almost complete block as sufficient indications for operation in injuries of the cord. Repeated tests for block are often necessary, particularly if the obstruction is increasing, so that operation may be promptly done when the block becomes complete and the nutrition of the cord is threatened by pressure.

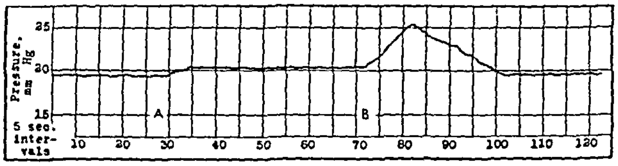

Fig 3 (G O'B, Dec 26, 1924)—Gunshot wound through disk between third and fourth dorsal vertebrae Bullet lodged in canal Complete paralysis Operation Cord destroyed Complete block Rise of fluid pressure on coughing shown *A*, jugular compression; *B*, coughing

A large number of spinal cord lesions are hopeless because of immediate destruction of the cord at the level of the injury. A few of these cases should be promptly recognized because of the vertebral deformity and clinical findings. Others with a permanent transverse lesion may show a subarachnoid block from local pressure and might be subjected to a useless operation. If the cord is completely crushed by the impact and this is followed by vertebral recoil, it may be that the tissue reaction will not be so severe as in cases in which

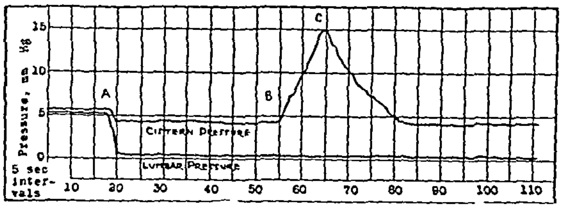

Fig 4 (J W, April 21, 1924).—Patient admitted five days after injury. Complete physiologic interruption below sixth cervical segment, with exception of spotted areas of tactile sensation to midpoint of thighs No demonstrable bone lesion Patient had both cranial and spinal injuries General condition bad. Double puncture showed a complete spinal block No operation Death in twenty one days *A*, removal of 2 c c of fluid by lumbar needle; *B*, jugular compression; *C*, pressure discontinued

there is less destruction and consequently more reactionary edema. If this is true, the Queckenstedt test in such a case will probably show no block of the subarachnoid space, or, at most, only a partial occlusion.

There is much unsettled controversy as to the advisability of operation in severe partial lesions of the cord. Here, I submit, the indications are founded on the demonstration of a spinal block. A severe incomplete lesion with pressure sufficient to block the subarachnoid space should have the pressure relieved to conserve such fibers as escaped destruction by the original injury.

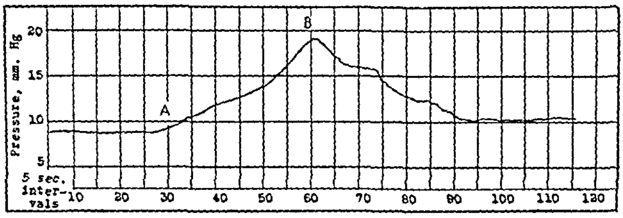

Fig. 5 (J. W. N.).—Fracture dislocation of first to fourth lumbar segments. Injury of three months' standing. Marked impairment with irritative symptoms. Chart shows high grade of incomplete block by Queckenstedt test. Fluid pressure required thirty seconds to rise to maximum, and thirty-five seconds to return to its original level. Down curve after release of jugular compression is halting, which is characteristic of cases of incomplete block. *A*, jugular compression; *B*, jugular release.

The technic of the Queckenstedt test should receive attention. In making the test, we have used as a routine the water manometer devised by Ayer. Sufficient time should be given after connecting the needle to allow the fluid to reach a steady level. This requires from one to three minutes. In some patients the mere placing of the hands on the skin of the neck preparatory to compressing the jugulars is followed by a rise of pressure in the lumbar manometer. This response has been attributed by us to the sudden fixation of the abdominal muscles of the patient in holding his breath or in his effort to brace himself for the anticipated compression of the neck. When the patient had a high lesion which was physiologically complete with paralysis of the trunk muscles, a rise of fluid in the spinal manometer did not occur from the mere touch of the skin of the neck. In a number of patients, jugular compression caused no rise in the manometer, while coughing or straining promptly elevated the fluid column (Fig. 3). Selling[6] called attention to this phenomenon in 1923, and concluded that the rise of fluid on coughing could not be used to exclude block.

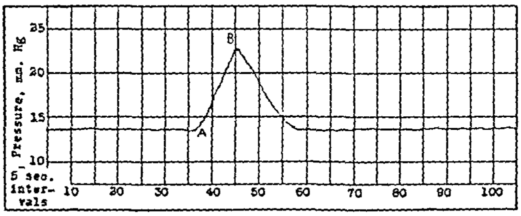

Fig. 6 (R. P., Oct. 6, 1924).—Comminuted fracture of fifth cervical vertebra. Complete physiologic interruption below sixth cervical segment. Queckenstedt test showed no block. Death thirty-three hours after injury. No operation. *A*, jugular compression; *B*, jugular release.

We have regarded the increase of spinal fluid pressure on coughing or straining as complementary to the Queckenstedt sign obtained by jugular compression. The rise of spinal fluid pressure on coughing results from a segmental venous back pressure below the obstruction of the subarachnoid space, and not from a rise of intracranial pressure, which is shut off by the block. This venous pressure below the level of the spinal block may be induced by raising the abdominal or thoracic pressure (Figs. 8, 9 and 10). In a few cases, notably with increased intracranial pressure, we have observed that the Queckenstedt sign is positive in the absence of spinal block. It is important to bear in mind this possibility in view of the occasional association of brain and cord injury. Cases with both head and spinal injuries may, with due precautions, be given the combined puncture of Ayer, which promptly confirms or eliminates a block of the spinal subarachnoid space and serves as a check to an erroneous interpretation (Fig. 4). No conclusions have been reached as to what effect the adoption of this test to secure evidence of pressure on the cord will have on the frequency of operation for spinal cord trauma. The decision for operation, even in cases with complete block, must finally rest with the clinical judgment of the surgeon when there are serious associated injuries or bad general condition of the patient from any cause.

Many patients with old cord injuries and severe disabling sequelae, if studied with methods that give actual information as to local compression, may be found to have lesions which operation may influence favorably (Fig. 5).

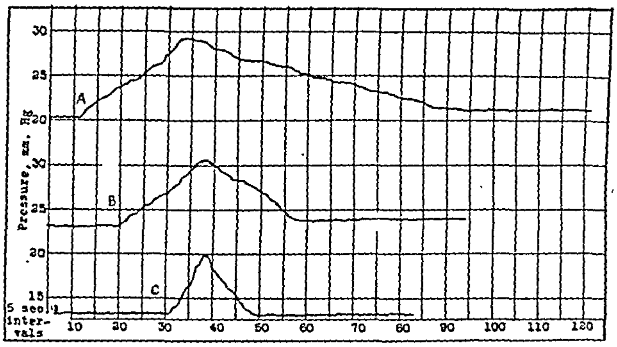

Fig. 7 (W. L., June 20, 1924).—Comminuted fracture of body of fifth cervical vertebra with forward dislocation of fourth cervical. Lesion almost functionally complete, but deep muscle sense feebly preserved in right foot and to a less degree in left. Prompt elevation of temperature. General condition unsatisfactory. No operation. Chart shows the spinal fluid pressure curves of three manometric tests. The first reading shows a high grade of block. The second, two days later, shows a partial recovery from the block, and the third, about twenty-four days later, shows that there was free passage of fluid in the subarachnoid space at the site of injury. The disappearance of the block may have been due to recovery from edema of the cord. Jugular compression: *A*, June 25; *B*, June 27; *C*, July 21.

Further experience with the test in cord injury is necessary to show what are its possibilities in the solution of some of the problems of cord edema. Reference is here made to the use of hypertonic solutions, which have a proved usefulness in the reduction of cerebral edema. Repeated tests for subarachnoid block in spinal injury might permit clinical deductions as to the value of such solutions in the less severe degrees of post-traumatic edema of the cord (Fig. 7). Demonstration of an early block might be followed in some cases by an operation in the four-hour period, which Allen believed necessary if cord incision was expected to reduce the edema. The main value of the test at the present time lies in its accuracy in demonstrating occlusion of the subarachnoid space. On the positive information thus obtained, the indications for laminectomy in cord trauma are immediately apparent. Of almost equal importance is the value of the test in excluding from operation those cases without pressure on the cord (Fig. 6). This is done by a simple procedure without risk to the patient. Since Jan. 1, 1924, the test has been used by us in fourteen patients for the purposes stated. In some of the earlier patients of this group, operation was done because we did not properly appreciate the significance of a total block in cord injuries. It was difficult also to abandon the attitude of extreme conservatism in dealing with this severe type of lesion which we formerly held. There were three patients admitted during this period in such bad general condition that no attempt was made to demonstrate a block. The number of patients on whom block determinations have been used as the main indication for laminectomy is too small and some of the cases of the group too recent for final conclusions as to what extent prognosis has been affected by use of the test. While the paper deals almost entirely with fracture dislocation of the spine, the test is useful in the study and diagnosis of penetrating injuries.

[6] Selling, Laurence: Localization of Spinal Cord Tumors, Arch. Neurol. & Psychiat. 8:27 (July) 1922.

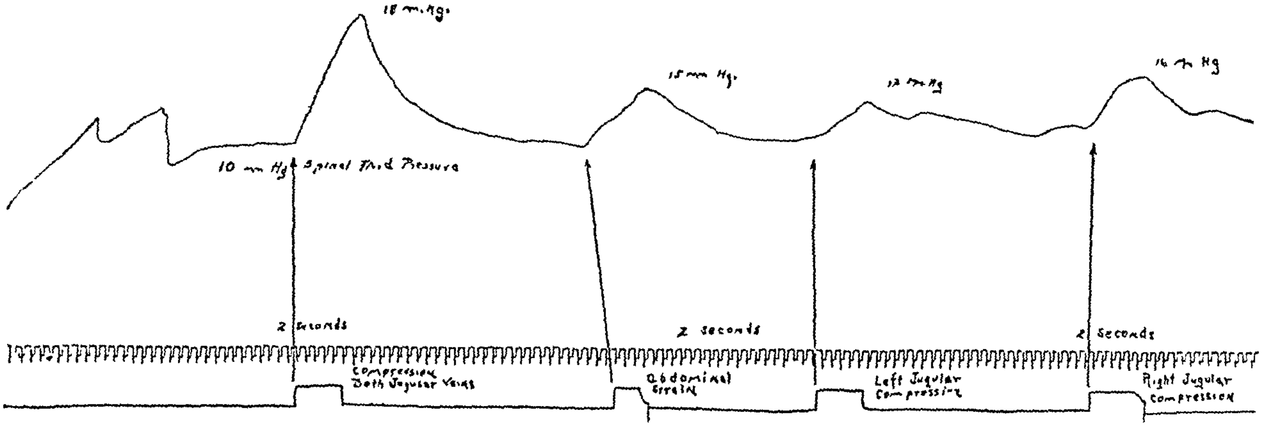

Fig. 8—Tracing of spinal fluid pressure made on patient who gave no symptoms of spinal block. In this tracing and in Figures 9 and 10 the prompt rise of fluid on jugular compression is shown with a more delayed fall on releasing pressure from the veins of the neck. The rise on coughing and on compression of the jugulars singly is shown. Compression of the left jugular in the three cases gave less response than did pressure on the right. Position of the patient in every case was horizontal and on the right side. The tracings were made by connecting the lumbar needle with a tambour.

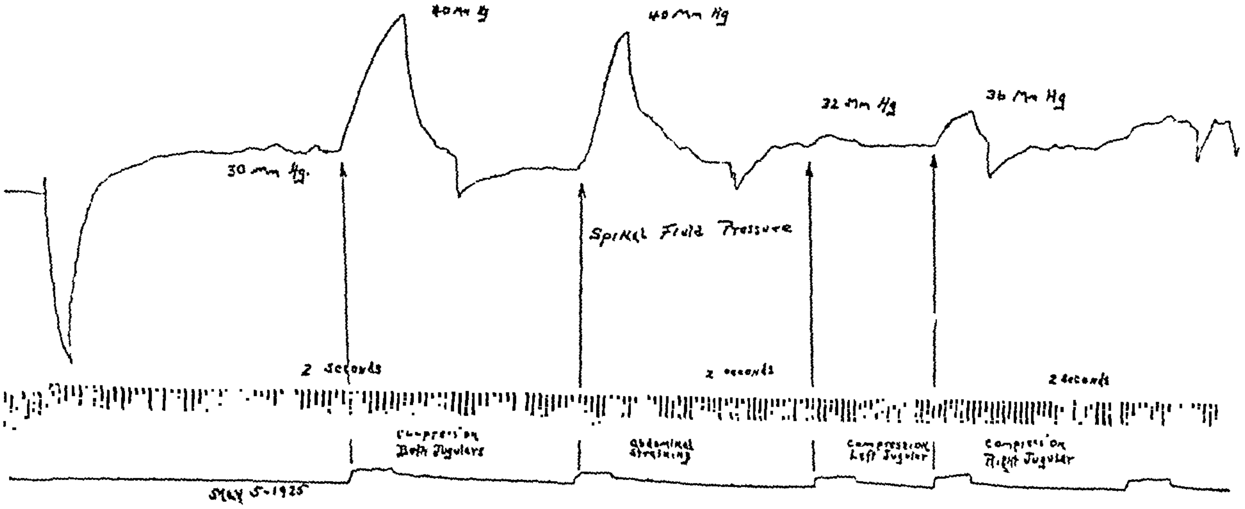

Fig 9.—Tracing of spinal fluid pressure made on patient who gave no symptoms of spinal block.

Of this series of fourteen patients with severe spinal cord injuries in which the test for subarachnoid block was used to determine pressure on the cord, the block was complete in seven cases and incomplete in four. Complete block as shown by the Queckenstedt test was verified by operation in five of the seven cases. Two of the patients were not operated on.

A brief report of some of these cases was made at the meeting of the Society of Neurological Surgeons in December, 1924, and the importance of subarachnoid block as the chief indication for operation was emphasized. The manometric tests in the cases reported are represented graphically on charts from pressure readings made by Drs. James G. Lyerly and Edmund J. Morrissey.

CONCLUSIONS

1. Clinical study of patients with severe spinal cord injuries generally fails to give early information as to the extent of the cord lesion.

2. Laminectomy for spinal cord injuries, except in penetrating wounds, is not indicated unless there is pressure on the cord.

3. Pressure on the cord following fracture dislocation cannot be demonstrated by clinical study or roentgen-ray examination unless there is considerable vertebral deformity.

4. Complete occlusion of the spinal subarachnoid space following injury should be taken to mean that the cord is compressed in a deformed or normal dural canal.

5. The demonstration of such compression of the cord by the Queckenstedt test or Ayer's combined puncture after spinal trauma should be considered an unequivocal indication for operation.

ABSTRACT OF DISCUSSION

Dr. Alfred W. Adson, Rochester, Minn.: Dr. Coleman has emphasized two very important points: the presence or absence of a block when the roentgen-ray findings are positive, and the presence or absence of a block when the findings are not positive. I have employed the Queckenstedt test, as presented by Dr. Coleman, in the diagnosis of spinal cord tumors, and it has proved of real value, since partial and complete blocks have been demonstrated when neurologic findings have been lacking. It is true that circumscribed arachnoiditis with the formation of cysts may give a complete block and be misleading in the diagnosis of a spinal cord tumor; but when this condition is present there is usually sufficient history to aid in the differential diagnosis. In my opinion, the Queckenstedt test should be of real value in helping to select operable cases. I have been rather conservative about exploring fractures and fracture dislocations of the cervical region, as some patients will recover spontaneously and others will improve by reduction of the dislocation. I have explored only those with definite pressure on the cord. Injuries of the dorsal region fail to respond well, whether or not surgical intervention is instituted. I am fairly enthusiastic about injuries of the cauda equina of the lumbar and sacral areas, since the injury is not a true cord injury, but an injury to the nerves; and, while there may be a complete block and the nerve may be seriously compressed, a good result may be obtained from a laminectomy. If the injury is of the conus, corresponding to the twelfth dorsal, the results from laminectomy are not always good; but if the neurologic level corresponds to the segmental level, that is, in about the second and third lumbar, a laminectomy is justified. If the roentgen ray reveals a fracture or a fracture dislocation of the twelfth dorsal, and the neurologic findings show an upper level corresponding to the lower dorsal segmental level, little is to be accomplished by a laminectomy. The subject is particularly timely, as a great deal of confusion exists about the surgical indications. Some surgeons are overenthusiastic and more or less radical; others are too conservative. If there is a possibility of accomplishing anything by surgical intervention, it should be instituted by all means, since without surgical intervention, little can be hoped for in many of these cases.

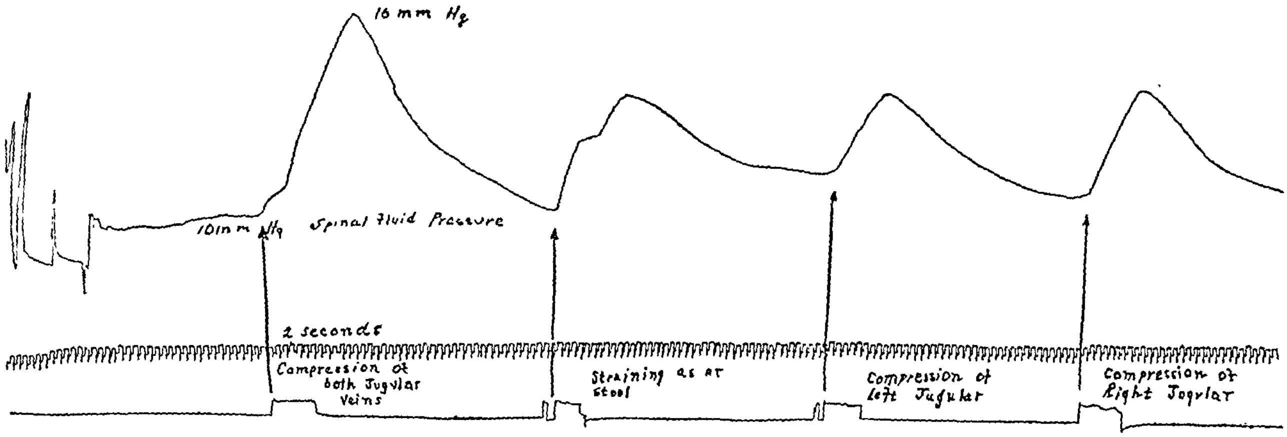

Fig. 10.—Tracing of spinal fluid pressure made on patient who gave no symptoms of spinal block.

Dr. Charles Bagley, Jr., Baltimore: In providing a common meeting ground for those favoring and those opposing operation in this group of injuries, this procedure as applied by Dr. Coleman will be useful in the management of spinal cord injuries. Because some cases with immediate slight cord injuries through edema and compression pass into the group of complete anatomic lesions, many have been unwilling to rob the patient of the chance offered by giving additional room for swelling and avoiding compression. The irreconcilables or what may be justly called radical surgeons will no doubt be comforted by the fact that through the employment of this method of diagnosis even the early stages of compression can now be detected. Dreading the late pathologic changes, I have made it a rule to operate in cases coming under observation early and I wish to call attention to five cases of fracture dislocation of the cervical vertebrae, in four of which there was evidence of complete physiologic block, while in the fifth case there was slight remaining function. Of the five patients, two adults operated on ten days after the accident died within a few days; a third one has not improved, though he is still living seven months after the operation. In none of these cases was the Queckenstedt test used, but the operation revealed a greater or less degree of compression in four cases. In the case in which compression was not revealed there has been no improvement.

Dr. Claude C. Coleman, Richmond, Va.: The discussions by Drs. Adson and Bagley emphasize just how far apart we are when attempting to settle the indications for operation in spinal cord injury on a basis of the clinical findings. For a number of years I have been bewildered by the conflicting statements from authoritative sources as to the indications for operation in acute injury of the spinal cord. The test for subarachnoid block furnishes the surgeon with a conviction which backs his course of procedure, whether he operates or whether he treats the case by conservative methods. I think Dr. Adson is quite right in excluding from consideration at this time the cauda equina injuries, which are really peripheral nerve lesions and should be operated on if the lesion is severe enough. My paper refers strictly to injury of the cord. I believe, however, that a patient with a cauda equina lesion will show a block if there is to be any benefit from laminectomy.

Tetanus Following Use of Bunion Pads as Vaccination Dressing.—Through investigations of the complications following vaccination against smallpox, eleven cases of postvaccinal tetanus which followed the use of bunion pads as a vaccination dressing have been investigated. Nine of these cases were fatal. Six of the physicians in whose practice seven of the ten cases of postvaccinal tetanus developed estimate that they had vaccinated approximately 700 persons on whom bunion pads were applied as a dressing. Bunion pads of the same varieties and from the same sources as those used in the cases which developed tetanus were collected from several localities. These samples were examined. Approximately 25 per cent. of these pads showed the presence of tetanus organisms. If the 700 pads known to have been used in the practice of these six physicians were contaminated with tetanus in the same proportion as those tested, it would mean that 175 persons were dressed with infected bunion pads and only seven, or 4 per cent., developed tetanus. In nine of the cases investigated, the tetanus followed a primary vaccination, while in two cases the data on this point are not available. It may, therefore, be significant that these cases all followed the cross-hatch or scarification methods of insertion, methods which undoubtedly tend to give more severe local lesions in primary vaccinations than are caused by the multiple puncture method.—Armstrong, Charles: *Pub. Health Rep.* **40**:1351 (June 26) 1925.

DIATHERMY IN JOINT INJURIES *

F. W. EWERHARDT, M.D.
ST. LOUIS

Our subject matter being diathermy, by which is meant "heating through," it will not, perhaps, be amiss to discuss first the more generally known forms of heat so that we may better understand and appreciate the distinct differences of effect produced by these various modes of heating human tissue.

We speak of heat as being conductive, convective and conversive. Conduction is that form of heat which is conveyed to the body by virtue of direct contact with a superheated substance. It is the old-fashioned household method of applying heat whenever that therapy seemed to be indicated. As examples of this form we make mention of the hot water bottle, hot poultices, fomentations, electric pads and hot baths. These appliances transmit heat to the part with which they come in contact by fact of contiguity. Convective heat radiates from a source approximating, but not in contact with, the body. Thus the heat emanating from the radiators in our homes or the superheated air cabinets are forms of convective heat. The numerous so-called bakers, be they heated by gas burners, electrical resistance wires or electric light, are only forms of convective heat. With respect to the latter, a qualifying statement is essential. Light, from the standpoint of a heat-producing agency, operates in two distinct and definite ways, which fact places it in two of our three groups. That part of the heat which is generated as a result of meeting resistance in its passage through the glass bulb and the air intervening between the source and the part to be irradiated is distinctly a form of convective heat, while the remaining rays, visible and invisible, striking the skin penetrate it, and meeting increased resistance are in turn converted into heat, thus forming and belonging to a third type; namely, conversive heat. This form may be defined as one in which light or electric energy, in its passage through human tissue, is converted into heat. Examples are the commonly known 1,000 watt deep therapy lamp, infra-red ray appliances, and the high frequency alternating current producing diathermy.

The reason for thus defining the various sources and forms of heat is to bring to our attention more clearly the necessity and value of discriminative application as applied to heat therapy. Properly used, the application of heat may be regarded as a valuable adjunct in the treatment of fractures and joint injuries. It seems wise, perhaps, to postpone that particular phase of our discussion at this time and consider for a few moments the mechanical aspect of diathermy.

By the term diathermy is meant the process of heating through the tissues as contrasted with convective and conductive heat, either of which operate, for the most part, by heating the tissue superficially and penetrating it very little. The source of diathermy is a high frequency current of high voltage and relatively low amperage. The strength of the current used may be any part from 100 to 3,000 milliamperes. The alternations or oscillations may range from one-half to two million per second and are so far removed beyond the point at which human tissue responds, either by muscular contraction or by electrolysis, that the result is a conversion of the electric energy into heat energy. For these reasons, it is not correct to speak of diathermy as being an electrical treatment per se. Electric treatment, as such, is always accompanied by a nerve response, muscular contraction or chemical reaction. This alternating current, which is also frequently known as the d'Arsonval current, is bipolar; that is, two electrodes are required, while the intervening tissue between them completes the circuit. By the use of suitable size and the proper application of electrodes, a knowledge of the desired amperage and duration of the current, the resultant heat may be localized and the intensity regulated almost at will.

The strength of the current is measured by an ammeter attached to the apparatus, which, for the most part, gives only an incomplete indication of the density of the current employed at the moment. The cooperation of the patient is a much more definite guide. The current is slowly increased to a point just beyond tolerance, or at least marked discomfiture, following which *it is diminished to a point at which the patient* will feel nothing but a comfortable warmth of the part treated. We have thus far spoken only of the so-called medical diathermy. Its object is to heat the tissues for the sole purpose of increasing the efficiency of the part treated. It is not destructive and is always within physiologic limits. By means of different types of electrodes and a change in the relation of voltage and amperage, the tissues may be so heated as to bring about destruction by desiccation or fulguration. This form is known as surgical diathermy, is extensively used, and is mentioned here solely for the purpose of properly identifying it and to avoid confusion.

The physiologic effect of these groups as thus defined may be briefly mentioned at this time. Superheated air, that is, convective heat and conductive heat which is produced by contact with a heated body, warms the tissues layer by layer much as a hot iron is heated in the forge. The immediate effect is a vasomotor dilatation followed by a venous stasis and frequently by free perspiration. The heat, however, penetrates barely beyond the dermis, for here the abundant vascular system dissipates it to other parts of the body. Wherever a relaxation of the superficial tissues is desired, this form of heat is indicated. Care must be exercised, however, to keep the temperature from rising beyond a point at which it becomes painful to the patient. If this occurs, the sensory nerve endings become temporarily paralyzed, which, although not particularly harmful, is nevertheless not desirable, for it tends to leave the tissues in an atonic condition.

The action of radiant light and heat for localized purposes is much the same as that of conductive heat just described, with this difference: The light rays possess a definite power of penetration, some deeper than others, and they are then converted instantly into heat, though here also a considerable quantity of it is carried off by the blood stream. Yet, as a result of penetration, much of the total volume is carried deeper into the tissues. For this reason, as well as for the ease, convenience, elegance and comparative cheapness, the modern 1,500-watt lamp is in popular demand. This apparatus is arranged in the shape of a parobolic globe, which causes the rays to be directed parallel to each other, thus avoiding a focal point and lessening to a minimum the probability of a burn. Incidentally, let it be mentioned that this modern type of lamp far exceeds in efficiency the commonly seen home-made contrivances. The latter lack the volume of illumination and the correct direction of the light rays that are so desirable.

---

* Read before the Section on Orthopedic Surgery at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

Diathermy, as stated before, is a mode of heating deep tissues by means of a high frequency current which passes from one electrode to the other in straight lines and affects whatever tissue intervenes. We have here, then, a method of heating the deep-seated tissues that cannot be obtained in any other known way, and should appeal to the surgeon who believes in the efficacy of the functional treatment of fractures and joint injuries.

Surgeons with hospital and clinical connections still see an undue number of poor end-results following so relatively simple a fracture as a Colles fracture. The limitation of motion present after five or six weeks of immobilization may be due to adhesions or fibrositis. If the former, it is necessary to break or stretch them before additional motion may be restored, in which case the preliminary heating of the tissues enhances the operation. It is in the earlier stages of the treatment that heating procedures are of immeasurable value to combat swelling, spasm and pain. The greater the swelling, the greater the chances of adhesions being formed, and also the greater the opportunity for fibrous degeneration of the muscle cells. Not only does the edema influence fibrositis, but the increased tension on the sensory nerves causes more or less pain, which in turn is responsible for muscular spasm. These factors, swelling, pain and spasm, interfere materially with the favorable progress of the condition. Spasm interferes with effort at reducing the fragments, and is probably the most potent factor in antagonizing efforts of mobilizing the limb. The lymph flow under normal conditions is extremely poor, its force being almost entirely dependent on muscular action and joint movement. Immobilization then hinders even this meager force by adding to the already existing tension, produced by the extravasation of blood and lymph from the injured vessels.

It is an established fact that heat in some form or other is a most reliable analgesic and a most dependable agent for the control of spasm; also that it increases the arterial flow as well as the return circulation, thus bringing quantities of fresh blood to the part and carrying away excess accumulation of débris. Yet many surgeons prefer not to recognize these factors. To say or intimate, however, that the treatment of a Colles fracture, for instance, along the lines of immobilization and without heat or other physical therapeutic measures, is not attended in all cases with a full measure of success would be absurd and untrue. But the fact remains that those of us who have opportunity to see many end-results, which may be classified from 75 to 25 per cent. disability, find on inquiry that, in the treatment instituted, no active measures were employed beyond strict immobilization.

Those who do believe in the efficacy of the functional treatment have also come to believe in the value of properly heating the tissues preparatory to movements and massage. It is in injuries of this sort, fractures, sprains, dislocations, subacromical or subdeltoid bursitis, and allied joint injuries, that we bespeak a kindly word for diathermy. Its sedative warmth imparts a feeling of comfort keenly appreciated by the patient. Its relaxing action on the muscles near the site of the injury makes proper massage and movement, as seems best indicated in each given case, infinitely more effective. It promotes the absorption of exudations and relieves the intercellular tension. The form of heat that brings this about most satisfactorily is diathermy.

In chronic, panfibrous and hemifibrous ankylosis, brasiere can best be accomplished if preceded by diathermy, followed by radiant heat to relieve the deep-seated congestion.

During the last ten years, more than 70,000 treatments have been given under our direction in the physiotherapeutic department of the Washington University School of Medicine. The patients treated were for the most part referred to us by the surgical and the orthopedic clinics. Our conclusions gathered from this experience supplemented by impressions gathered from others of like experience leads us to these conclusions:

CONCLUSIONS

1. Diathermy is a safe heating procedure which can be localized in deep-seated tissues at will; the degree of intensity may be satisfactorily regulated by means of suitable electrodes of varying sizes, properly applied, and augmented by the cooperation of the patient.
2. It is a valuable measure to at least partial control of pain, spasm and swelling in the earlier stages of fractures and joint injuries, and contributes, therefore, materially to a favorable functional end-result.
3. Patients take kindly to it, they are favorably impressed with the procedure, and their cooperation is more easily secured when movements and massage are indicated.
4. Unquestionably, the period of convalescence in the treatment of fractures is materially reduced.
5. Its application seems indicated in postoperative bone and joint conditions, acute sprains, fractures and bursitis; when brasiere is found necessary; in acute and chronic arthritis, and in treating contractures and fibrositis.
6. It is contraindicated in cases of pus sac without drainage, when there is danger of hemorrhage, and in tuberculous joints and suspected malignancy.

5204 Kensington Street.

ABSTRACT OF DISCUSSION

Dr. H. D. Corbusier, Plainfield, N. J.: I have had considerable experience in using this modality. Restriction or limitation of motion of joints is an old story. Those of us who have obtained marked results from the use of nonoperative procedures are quite impressed with the value of diathermy. I use diathermy daily for treatment of limitation of joint motion in all joints of the body. The most numerous cases are in the knee, and in the wrist when there has been poor splinting of wrist cases; in so-called focal infections; in infections following the infectious diseases, and in obscure cases with no cause to be found. The introduction of heat deeply into these joints, which are at times firmly fixed in flexion, is a wise and satisfactory procedure. Diathermy is the only method by which this can be done. My technic is, first of all, to give heat superficially; that is, in the case of a knee we give the leg whirl; in the case of an arm we give the arm whirl, and then follow with diathermy. Of course, adhesions may reform, but I have failed to see many cases in which diathermy was not successful; that is, perhaps not forming a complete cure, but relieved to such an extent that one could use the words "a success" in speaking of them.

Dr. M. T. Koven, Brooklyn: It is very interesting in a discussion of diathermy to think of its value in the treatment of arthritis. We have found from experience that the treatment of gonorrheal arthritis by diathermy is almost a specific. We apply the diathermy not only to the joints involved but also to the focus of infection. In recent literature, one reads quite a bit of the treatment of poliomyelitis with diathermy. We have followed out that method whereby we are inducing diathermy at a part in the spine at which there is pathologic change and at the same time heating the leg or arm that is involved. Thus far our results have appeared to be very satisfactory. We are treating a man who has a traumatic transverse myelitis, sustained in an automobile accident with a resultant complete paralysis below the waist line. Diathermy is applied with the plates at an area corresponding to the lesion, and we find that, when the current is applied to the spine, the patient gets a sensation of impulses at the terminal extremities and there is considerable improvement in sensations and motor power.

THE AVERAGE SEX LIFE OF AMERICAN WOMEN

RELATION BETWEEN EXPERIENCES AND GENITAL FINDINGS: I. INTRODUCTION TO STUDIES[*]

ROBERT L. DICKINSON, M.D.
Secretary, Committee on Maternal Health
ASSISTED BY
HENRY H. PIERSON, M.D.
Instructor in Anatomy, New York University
NEW YORK

It is probably well within bounds to affirm that our present beliefs concerning normal sex life and average experience and practice have the status of surmises standing on foundations no more secure than general impressions and scattering personal histories. It is time we began building on collected case records running through lifetimes in series counted in tens of thousands. In view of the pervicacious gonad urge in human beings, it is not a little curious that science develops its sole timidity around about the pivotal point of the physiology of sex. Perhaps this avoidance—not of the bizarre and the extreme, the abnormal and the diseased, but of the normal usages and medial standards of mankind—perhaps this shyness is begotten by the certainty that such study cannot be freed from the warp of personal experience, the bias of individual prejudice, and, above all, from the implication of prurience. And yet a certain measure of opprobrium would not be too great a price to pay in order to rid ourselves of many phallic fallacies. Our vigorous protests against the sensual detail of pornographic pseudoscience loses force unless we ourselves issue succinct statistics and physiologic summaries of what we find to be average and believe to be normal, and unless we offer in place of the prolix mush of much sex literature the few pages necessary for a standard of instruction covering sex education. Considering the incorrigible marriage habit of the race, it is not unreasonable to demand of preventive medicine a place for a little section on conjugal hygiene that might do its part to invest with dignity certain processes of love and begetting.

As to gynecology, it seems to have been too much busied with the operative work that constitutes nearly one fourth of major surgery to give proper time to certain fundamentals. We have trained students and interns with an outlook on laparotomy and pathology rather than on physiology, life-adjustments, and pelvic social problems. So far, the subdivisions of the incipient science of preventive gynecology have been better obstetrics, cancer research and control, and venereal disease restriction.

A plan has been suggested for a council to coordinate the work of the following organizations:

AGENCIES CONCERNED IN SEX PROBLEMS

1. Committee for Research on Sex Problems (under National Research Council); assists a number of special researches, chiefly on animals, and conducts a medical psychopathologic office study.
2. Bureau of Social Hygiene; surveys and assistance in sex problems; endowment over a million dollars.
3. American Social Hygiene Association, propaganda, sex education, combating prostitution and venereal disease, $200,000 a year.
4. Committee of Fourteen, New York (of Fifteen, Chicago; of Twenty, Utica); investigation of sex vice conditions and watch on legislation; about $15,000 a year in New York City. New York Society for the Suppression of Vice: to enforce obscenity laws; about $15,000.

5 and 6. Department of Eugenics and Eugenics Record Office, Cold Spring Harbor (under Carnegie Institution of Washington); studies in heredity.

7. Committee in Eugenics and Dysgenics of Birth Regulation (under Eugenics Committee of United States); sociological studies; newly organized.
8. Committee on Maternal Health (medical); study by clinics and research in contraception, sterility and sterilization; $21,000 in its second year, 1925.
9. American Birth Control League; publicity; amendment to state laws; clinic; some $60,000 to $80,000.
10. Voluntary Parenthood League; amendment to federal law; about $20,000.
11. Committee on Maternal Welfare (representing American Association of Obstetricians, Gynecologists and Abdominal Surgeons; American Gynecological Society, and American Pediatric Society); prenatal and postnatal care; death rates; puerperal fever; small funds.

Churches and Christian associations, social agencies and public health organizations; schools and colleges; courts and legal societies; medical institutions and societies; biologic laboratories.

THE NEXT STEPS

The Committee on Maternal Health found that, as soon as it had surveyed the field and persuaded seven clinics to work out contraception studies—indications, methods and results, and related sterility and sterilization—steps must be taken to develop essential data not available. Among these missing facts may be mentioned age at marriage and at childbirth, by single years, for American women; duration of their reproductive life, with fecundity and fertility; the findings that make, or point to, the diagnosis of sex experiences; exact genital measurements; the anatomy of the sex act and the bearings of it on health; together with the correlation of pelvic disorders and diseases with sex practices of all kinds—the whole based no longer on opinion, but on trustworthy medical records. This paper is an introduction to the series, covering several thousand histories.

As an important preliminary I propose the first summary of an epoch making and elaborate study published by Katherine B. Davis, Ph.D.,[1] for the Bureau of Social Hygiene.

AUTO-EROTIC PRACTICES

From the anonymous answers received from a questionnaire sent to American college women living in city, town and country, 1,183 reports were summarized. The average age was 37, the largest group, 30. Two thirds of these unmarried women report the practice of masturbation. One third of the total number continue the practice. More than a third of those that started stopped within a year. Among the total auto-erotics, half carried on from ten to twenty years, while of those that continue, a third have kept on from twenty to thirty years. The practice commenced for the most part between the ages of 5 and 11 (42 per cent.), that is, well in advance of puberty, while before reaching 16 nearly 60 per cent. of those practicing had begun. The mode or peak of the beginnings is at the eighth year (Fig. 1). Herein lies a notable contrast between male and female, since three fourths of the males start between 12 and 17. As for orgasm, though the term was not always understood, it seems to be late in developing, since its appearance is listed, in 62 per cent. of those reporting, as beginning at or after the eighteenth year. The two chief reasons given were, first, to secure pleasure (with no great difficulty in stopping) and, second, the desire for relief from tension, or else an uncontrollable impulse for release, with unsuccessful efforts to break off. The two classes were nearly alike in their membership. Suggestive reading is listed as a rather minor excitant, and very little blame is laid on "spooning" or dancing.

---

[*] Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

[1] Davis, Katherine B.: Study of Certain Auto-Erotic Practices, Ment. Hyg. **8**: 668-723 (July) 1924; **9**: 28-59 (Jan.) 1925; A Study of the Sex Life of the Normal Married Woman: I, The Use of Contraceptives, J. Soc. Hyg. **8**: 2 (April) 1922; II, The Happiness of Married Life, ibid. **9**: 1-25 (Jan.) 1923; III, The Happiness of Married Life, ibid. *9: 129-146 (March) 1923.*

In the matter of frequency, one third report once or twice a month; with a fourth it is less often; with a fifth, once a week; but the duration of the practice at this rate or oftener is not given.

A correlation between masturbation and health at the time of reporting, in a list that covers the third that never experimented, the third that discontinued, and the third that continue, shows a "real difference" in the way of better health among those keeping on with the practice. Moreover, there is no appreciable difference in health between those who began early and those who started after 18. Effects called "good" and "negative," when grouped together, give 61 per cent. Not one in ten asked advice about the habit. Cessation was brought about as follows: One third, for fear of results; one third, because of feelings of shame or wrong-doing; and one fifth outgrew the habit.

RELATION WITH OTHER SEX PRACTICES

The relations with other sex practices are given in percentages, with the figures for the married group in brackets. All sex experiences denied, either auto-erotic or homosexual or heterosexual, 30 per cent. (51); sex intercourse only, 1.3 (2); homosexual physical relation alone, 4.5 (8); masturbation only, 42 (27); both masturbation and homosexual experiences, 12 (6.5); masturbation and sexual intercourse, 7 (3.6); all three, 2.6 (1.3); total who had had sexual intercourse, 11 (7); total who had homosexual relation, 19 (16). Total masturbation at any time, 65 (38). Finally, it is to be noted that about one third of those who have masturbated have had other sex experiences.

As this large group represents a type of intelligent womanhood known to be busied in productive occupations, and reasonably assumed to be trained in self control, and as its admissions are probably minimal for the group or for less trained women, it seems to me a fair inference that auto-erotic practice is rather average experience among women and that moderate usage may be called a normal sex experience. Two important bearings of these new data on sex education lie in the need of beginning of instruction before five years of age, and the ability to remove much unnecessary mental castigation.

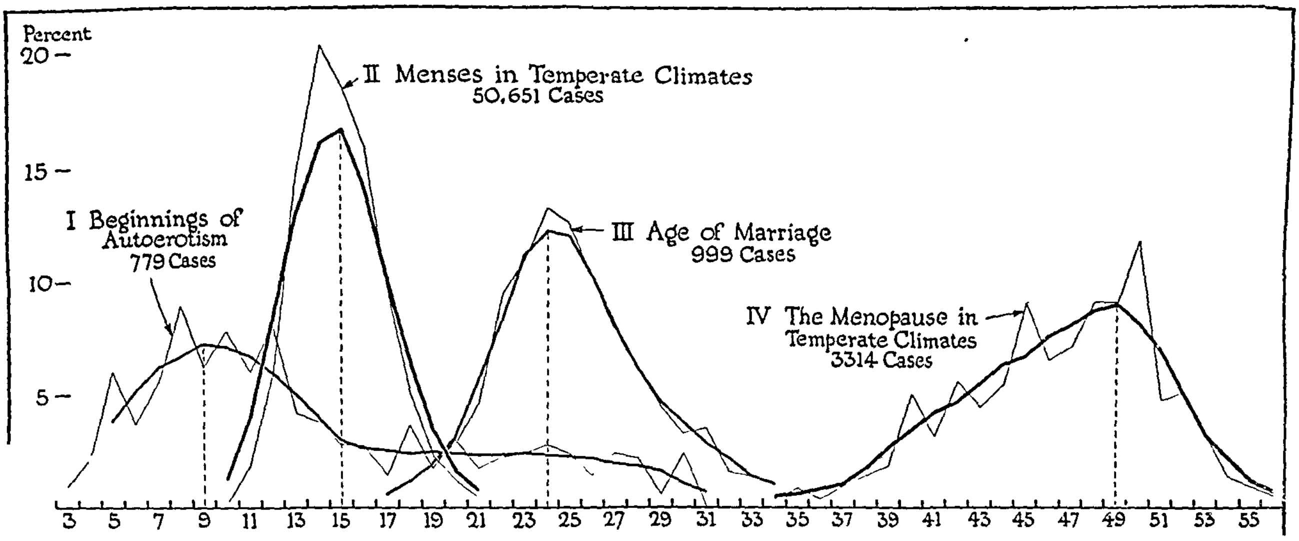

Fig. 1—Main periods of sex life of women of the temperate climates: Information concerning auto eroticism and marriage was obtained from ated Americans, on the beginning and ending of menstrual life, from a number of countries, from which our women differ by starting some earlier and finishing later, as shown in other charts. The curves have been smoothed on a four year center, excepting the marriages. The features are the early age at which masturbation must be watched for, and the wide span of both puberty and the menopause. In both, late and late finish assume large proportions The menopause is much nearer 50 than 45. The peaks at round numbers, such as 45 and 50, show untrustfulness of any memory other than recent.

MARRIAGE

Dr. Davis' married group of 1,000 averages 38 years old, with 70 per cent. college graduates. The median age at marriage was 25.7, and the number of marriages reported as happy, 87 per cent. Half the number report pleasurable sex relations throughout their married lives, the average duration of marriage being twelve years. Two thirds started pleasurably. One third showed alteration in feeling thereafter, the gains and the losses apparently very nearly balancing. The difference in pleasurable relations between those instructed before marriage and those not instructed was found to be significant, however meager the instruction. About one in twenty mention reception of information on birth control. A previous habit of masturbation did not have any effect on initial sex relations, and in the early years of marriage pleasurable reactions were significantly higher, but responsiveness persisted longest in the group that never masturbated. To judge by known cases, a fourth continued the practice after marriage. Among the fourth to whom the sex relation was distasteful, apparently about equal responsibility belongs to states of mind, to frigidity, and to faults of the husband. Fear of pregnancy plays little part, and mention of previous masturbation as a cause is notable for its absence.

The degree of intensity of the sex impulses of the wife as compared with those of the husband gave 31 per cent. as "about equal," the wife's greater in 3.5 per cent., and the husband's greater in 62 per cent. The frequency of desire ran close to these ratios in husband and wife. In frequency of repetition of coitus, the average comes somewhere near twice a week, as nearly as I can make out from the tables. Intercourse continued during entire pregnancy in 25 per cent., and from a few weeks to seven or eight months in 60 per cent.

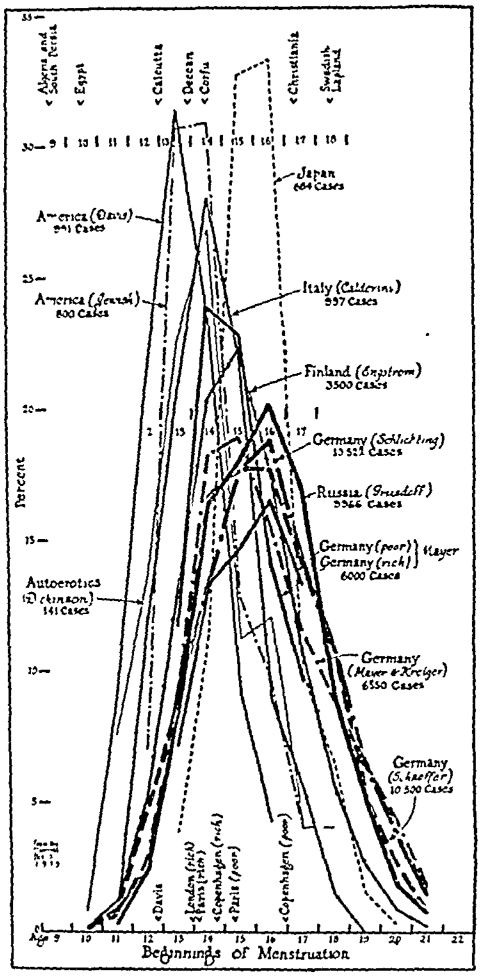

Fig. 2.—Data from which the general curve of Figure 1 is compiled. The records of 50,651 puberties are shown, to contrast various countries and climates and classes, the poor and the rich, the well nourished and the well educated. For each group reported, one should know details of the conditions of nourishment and nervous system and prosperity and, possibly, sensual stimulus, though the auto erotic subjects here are no earlier than their other American sisters. Finland, as a cold country, calls for explanation, with its early start. Darker lines indicate larger numbers.

CHARTS OF SEX LIFE

As an example of what is under way in the new plan of getting averages or standards, we have assembled on a graph (Fig. 1) the times of occurrence of the beginning of sex consciousness, of puberty, of marriage, and of menopause, finding the pointers toward a good deal of material in Kisch.[2] Where sufficiently numerous, American data alone are used. Where there are few from this country, as in the matter of the menopause, 3,200 cases from other temperate climates have been charted and the 332 American cases compared with them before plotting the larger number as an average.

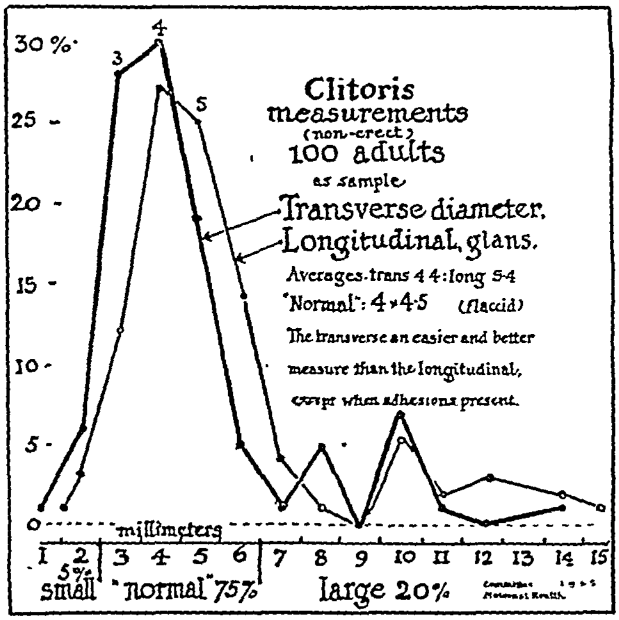

Fig. 3.—The utility of charting frequencies. Because the "average" is used in the anatomies in giving these diameters, other authors would class this largest group as "small" organs Morris gives 8 mm., for instance, as average.

The verification of figures and curves and the smoothing of curves have been in expert hands. The marriage curve is drawn only from American college and club women because of the absence of data by single years for Amercan women in general.[3]

We learn from this diagram that instruction concerning auto-eroticism must begin long before the time we had supposed. The curve rises rapidly from the fifth year and reaches its peak at the eighth. We learn further that to stress 13½ or 14, the average age for the menses to begin, is misleading when so large a proportion (among the 50,651) belong earlier, and a still larger group later. Even more markedly is this width of spacing true of the menopause. The skewness of this curve is striking. We have been teaching our patients to look forward to release at 45. Here we see that the greatest frequency is 49. These and other instances of the practical utility of applying modern statistical methods to our special work will be discussed more fully later.

MISLEADING PRESENT FIGURES

Only by charting can one acquire ideas of proportion. Thus, one discovers how misleading the term "average" may be. One learns to ask always, "What is the more frequent dimension or grouping?" This was shown when we started to inquire what constituted a normal or average clitoris. About the genitalia even anatomists are loose in their statements, the diameters running from 8 mm. (Morris) to 6.7 (Testut) and 5.6

---

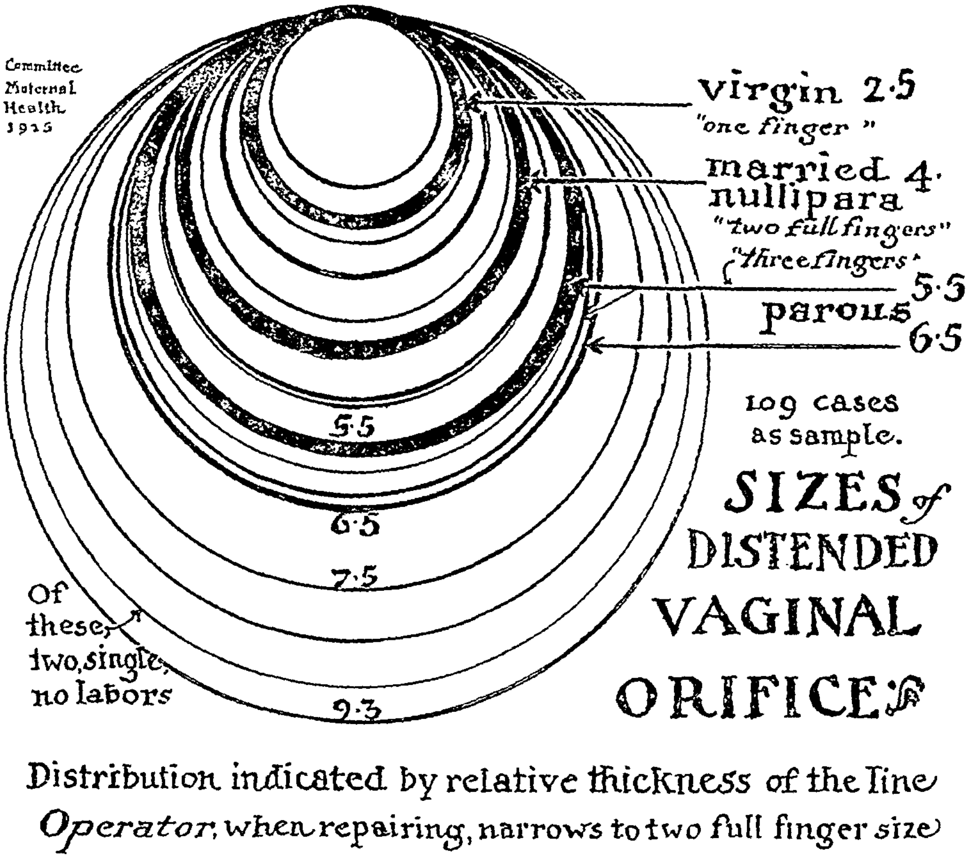
[3] In our reprint and in the Transactions of the Section, separate graphs will show the multiple lines of the many sources from which this chart is made up.

(Waldeyer, Poirier, Jayle). This is because they had on a list a few scattering large examples. A graph of distribution of measurements shows strikingly that 4 mm. is the greatest frequency of both diameters of the glans, and exhibits the way the transverse measurements consistently group lower than the anterior-posterior. The genitalia have been the subject of no proper study of types and dimensions.

RELATIONSHIPS

We are studying the following propositions, among others, in subsequent sections.[4]

The dimensions and appearance of the hymen and of acquired hypertrophies about the vulva and vagina furnish much more diagnostic evidence of sex experience than is commonly apprehended.



Committee Maternal Health 1925
virgin 2·5
"one finger"
married 4·
nullipara
"two full fingers"
"three fingers"
5·5
parous
6·5
109 cases as sample.
SIZES of DISTENDED VAGINAL ORIFICES
5·5
6·5
7·5
9·3
Of these, two, single, no labors
Distribution indicated by relative thickness of the line
Operator, when repairing, narrows to two full finger size

Fig. 4.—Distribution of an unselected series of introitus distensibilities from office practice. To be of value, there should be three times as many in each series; but the trend is shown.

The untouched hymen admits no more than the average adult forefinger. Thus stretched, the edge is sharp to the touch, the sensitiveness well defined. Sharpness of edge disappears only from tearing or from a process of gradual stretching, and, if the distention is gradual and neither excessive nor too prolonged, will return.

Openings of the hymen larger than one finger are the result of one of the following agencies: douching, gynecologic treatment, coitus, delivery or vaginal friction.

Under graduated, oft-repeated stretchings, degrees of elasticity or distensibility may develop sufficient to allow the passage of a full sized head or of the adult hand without a nick of hymen or injury to other structures. Such fully dilatable, undamaged hymens, close or open, belong to the vigorous coital or manual massage groups. Either head-stretch or hand-stretch may produce the gaping vulva.

Well marked acquired hypertrophies about the vulva are auto-erotic evidence.[5] These consist in largely developed labia minora and prepuce, laid in many-wrinkled, darkened folds, sometimes studded with outstanding sebaceous glands; in tabs of the meatus; in prominent veins; in active pelvic floor muscles; and, infrequently, in an enlarged clitoris.

Vaginal distensibilities and surface appearances, particularly in the nullipara, give clear evidences of marital or extramarital overindulgence, or actual or relative impotence or neglect.

THE VAGINAL ORIFICE

Measurements and classifications show the main groupings to be the conventional ones; namely, virgin, wife and mother. With these our histories develop standard diameters of 2.5, 4 and from 5.5 to 6.5, respectively. To the three groups (1) intact, unentered hymen, (2) married nullipara (or cohabiting imparous single woman), and (3) parous woman we add (4) the nulliparous orifice of very vigorous coitus; (5) the virgin orifice massaged to various dimensions—some among the largest—and (6) the parous orifice that seems to owe its immunity from damage to hymen or tear of pelvic floor to the oft-repeated stretch of one or both the foregoing experiences. For the crucial test of the intact hymen, that is, one free from entry by adult phallus or from finger frictions, it is shown that appearance — except for gross tears—counts less than sharpness of edge and sensitiveness taken in conjunction with diameter under distention. The measurements were made by using the finger or fingers as calibrator, noting the depth of entry on the digits, or by the passage of graduated glass cylinders. The hymen edge was studied (for our drawings that were all made life size) by passing and then partly withdrawing a glass ball in order to spread the membrane out, or else by a cotton wad held in forceps. Vaginal profile diagrams were drawn full size by using the subpubic arch as the point of departure for measurement and direction, with the patient either in a knee chest posture with the sound, or in the dorsal posture. The fourth method was the glass test tube of average phallic diameter (3.3 cm.) to observe visually the vulvar and intravaginal mechanical factors. Thereby a vaginismus is observed through the bottom of the glass to be due to a tight hymen or spasm; or seen to be caused by impingement of the tip on an unusually deep or stretched and reddened fossa navicularis; or else with ample vaginal orifice, it is noted, through the anterior wall of the glass, that the meatus is, or when pushed on, becomes vaginal in outlook, and therefore in coitus is spread wide open and traumatized. Lastly, a raw cervix in the vaginal axis may be seen through this speculum to be the tender target.

BIRTH CONTROL

We have some definite figures concerning the prevalence of the practice and evidence of the standing of birth control among women of fine type. Among the first thousand answers to the Davis questionnaire, only seventy-eight expressed disapproval of any means to prevent conception. Approval "in principle" was expressed by 73 per cent., and these employed some form of contraceptive and averaged 1.9 children and 2.5 pregnancies each. Abstinence belonged to 8 per cent. Of the remainder it is not possible to say how many were sterile, but Dublin's[6] 20 per cent. sterility for New York City, and the proportion of childless homes reported from Philadelphia would make it not unlikely that, save for the abstinents, those who used no preventives had no reason to do so. One infers also from the tables that economic and health reasons in nearly equal proportions influenced 70 per cent. of the users of contraceptives. To 37 per cent. of those instructed information was given by physicians.

Though it forms an important section under the title of our paper, the order of popularity of the various measures and the percentages of safety need not be taken up here, as they have been fully discussed in the first report of the Committee on Maternal Health,[7] drawn from the figures of the London and New York birth control clinics and from the Davis group and covering about 4,700 cases in all. The unreliability of these returns calls for the real investigation of efficacy and harm or harmlessness which is now under way in university and other clinics. These studies, and the investigation of the indications and of the field of sterilization, and the researches on methods that would do away with the present mechanical schemes, should, in time, give the committee adequate definitions and a proper array of evidence of value.

CONCLUSION

As we began, we conclude. Organized study of certain neglected aspects of human sex physiology and practice are due and overdue. There is a part of this investigation that can be cared for only by the medical profession. Shall the American Medical Association have any representation in these activities?[8]

438 West One Hundred and Sixteenth Street.

ABSTRACT OF DISCUSSION

Dr. James F. Cooper, New York: I represent the American Birth Control League of New York. I was called to undertake clinical research work and to direct the activities of that department. We have been conducting a clinic for the contraceptive treatment of married women, who under the laws of the state of New York are entitled to that advice. Four thousand cases have passed through that clinic and we have collected quite an amount of data in regard to the normal and abnormal sex life of women. Our experience deals with another class of people from that reported by Dr. Katherine Davis. She had the intelligent class, whereas ours are very largely drawn from the ordinary dispensary type of patient. The information we have received from them in regard to the normal sex habits coincide pretty much with the report made for this other group of women. I think what Dr. Dickinson has given might be considered as a cross section of the life of the average American woman in sex matters. The one big thing I want to emphasize at this meeting is what Dr. Dickinson brought out, namely, we have lay organizations undertaking the work which should be undertaken and sponsored by the medical profession. The request came to the organization for certain gynecologic information, and we found there was no reliable information to be given. On that account a research department was instituted to investigate the various contraceptive methods with the idea of learning their relative values and respective merits. This was a lay organization, but soon it became evident that the scientific side was necessary, so a small group of physicians was brought together to undertake that pioneer work, which has been going on for three years. I am the person Dr. Dickinson referred to as the member of the committee who wanted the medical profession to take up the work and to study the scientific problem of contraceptives and also the sex problems that are presented from time to time. When the time comes that our professional people will take up this subject adequately, our birth control clinic will have no need for further existence. Until then we are going on with the scientific work and publishing reports which can be secured by any physician on application to the organization; but the point *I wish to make is that it is a matter for scientific study.* Too many times, when I bring this matter before medical societies, it is looked on with disdain. With the terrible mortality we have in obstetrics and with the great morbidity, I feel we can never reduce to any extent the 20,000 maternal deaths each year until we are able to study our cases and find out the causes that contribute to this enormous mortality and until we study these cases and give to those who are rightly entitled to it the contraceptive information needed rather than *turn them aside without giving proper information.*

Dr. Robert L. Dickinson, New York: My advice is to start clinics for the study of these sex problems, contraception, sterility and sterilization, with emphasis on sterility, as it is an important factor. Quite recently a statistical study from the Metropolitan Life Insurance Company showed that one out of every five marriages in New York City is sterile. Regarding sterilization of the unfit, H. H. Laughlin of Cold Spring Harbor is the authority. No contraceptive information of any value can be obtained in Holland. We are trying to find out how France restricts its births. I hope this section will take an interest in those scientific investigations of sex that are basic. Our first paper today took up the latest discovery in the physiology of sex; our new study takes up the most neglected and interesting matter in obstetrics and gynecology.

Color Vision Among School Children.—As a part of the examination of 12,000 school children in Nassau County, N. Y., New Castle County, Del., Porter County, Ind., Frederick County, Md., and in Spartanburg and nearby mill villages in South Carolina, the color vision of each child was tested. Holmgren's wool test was used. Naming of the colors was not required, but only the ability to sort similar colors As the distinguishing of delicate shades was not required, only the more pronounced cases of defective color sense would be found. Two per cent. of the boys were affected, as against about 0.25 per cent. of the girls. Defective color sense of the type found among school children does not seem to be associated with visual acuity.—Collins, S. D.: *Pub. Health Rep.* **40**:1521 (July 17) 1925.

[7] Contraception—Medical Review of the Situation, Am. J. Obst. & Gynec. **49**:95 (Nov.) 1924.

[8] At the meeting of the Section on Obstetrics, Gynecology and Abdominal Surgery, May 29, 1925, Dr. Dickinson offered a resolution, in the form of a motion, that the chairman of the section appoint a committee to consider the matter of cooperation with other responsible organizations on the study of sex problems. The motion was seconded by Dr. J. C. Litzenberg, Minneapolis, and carried (The Journal, June 13, 1925, p. 1833). The author also offered the following resolution, which was seconded and carried: "*Resolved,* That this section hereby recommend the alteration of existing laws wherever necessary so that physicians may legally give contraceptive information to their patients in the regular course of their practice."

PERIRENAL SCLEROSIS (CHRONIC CICATRIZING PERINEPHRITIS)

REPORTS OF TWO CASES OCCURRING AS A SEQUEL TO PERINEPHRITIC ABSCESS *

VINCENT J. O'CONOR, M.D.
CHICAGO

Perinephritic abscess has been the subject of extensive review in medical literature. On the other hand, the more chronic inflammatory conditions which result in sclerotic thickening of the renal capsule have received but slight consideration.

Inflammation of the fibrous and fatty investment of the kidneys, perinephritis in the narrower sense of the term, may accompany all the acute and chronic processes that disturb the kidney; and depending on the variety of the inflammation, leads to thickening, adhesions with the renal parenchyma or subcapsular suppuration.

Whether extensive perirenal suppuration occurs or not, a persistent indurative process may continue until the perinephritic fat and fibrous capsule of the kidney become converted into an unyielding cicatricial shell.

Hartmann,[1] one of the earliest writers on this subject, considers that nonsuppurative perinephritis is an important pathologic entity because of the adhesions which it causes between the kidney and surrounding organs. He describes this as being characterized in its slight forms by a simple thickening of the capsule with induration and adhesion; in the more severe types there may be veritable sclerolipomatous tumors formed around the kidney; the thickened hardened fat may even invade the kidney, especially in the region of the hilum, by the substitution of sclerolipomatous tissue around the calices.

Hartmann, Carswell,[2] Dupuytren[3] and Bricheteau[4] have reported cases in which thickening of the renal capsule has resulted in an invasion of almost the entire substance of the kidney itself.

Fürbringer[5] states that when the perinephritic process is of long duration, and tends to recovery, *fibrous encysting and thickening* of the surrounding tissues are observed and the kidney may become atrophic.

Kolischer[6] says: "After the acute stage [of infection] has passed, the inflammatory infiltrations may become organized and finally be transformed in fibrous, cicatrical tissue. Either this fibrous transformation of the perinephritic fat may lead to compression of the kidney, or the formation of cicatricial strands may attach the kidney to other intra-abdominal organs and may also dislocate the kidney by their progressive contraction, or both conditions may be combined."

Keyes[7] says that the protective type of perinephritis is seen to a greater or lesser degree in connection with every chronic suppuration within the kidney or its pelvis; for it consists of nothing more than a round cell infiltration and subsequent sclerosis whereby the connective tissue, with the fat in its meshes, becomes more densely adherent to the kidney over the surface. But this process, if long continued, leads to cicatrization with fatty degeneration, whereby the kidney envelop is changed into a dense mass of scar, yellow with contained fat, the fat being a hard mass held in the meshes of the scar tissue.

It is not my purpose in this report to provoke further discussion as to the route by which infection may reach the perinephrium. Older writers[8] support the theory of the origin of perirenal suppuration as being within the kidney. More recent work[9] tends to the belief that septic material is more frequently deposited in the renal cortex and perinephrium by the blood stream. Since the blood supply of the perirenal tissues is independent from that of the kidney proper, it is possible that infection may be deposited there without otherwise affecting the kidney.

Herringham[10] believes that injury can damage the perinephric structures. There may be hemorrhage between the capsule and the kidney or into the perirenal tissues independent of the capsule. If low grade infection occurs in the hematoma, a gradual organization and fibrosis may result.

The lack of data regarding the effect of renal compression from surrounding layers of cicatricial tissue tends to the conclusion either that the process rarely progresses to the extent of producing subjective symptoms or that it has been disregarded as a possible cause of renal pain.

W. J. Mayo[11] reports: "I have been slow to admit that capsular compression of the kidney could be the cause of symptoms. . . . In our experience, decapsulation has been valuable in this small group of cases in which there are scars and lime deposit in the capsule of the kidney."

The symptoms produced by this indurative type of chronic perinephritis are the result of renal compression or displacement.

Dull aching pain localized in the region of the affected kidney is frequently the only subjective symptom. When abnormal attachments are lacking there is usually no abdominal discomfort. Since the fibrous encasement of the kidney prevents its normal adjustment to increased vascularity, the ingestion of large quantities of fluid may cause a temporary increase of pain in the affected kidney.

The diagnosis of this condition is reached by the process of elimination. As a rule, there are no urinary symptoms, and a continuous dull ache in the renal region is the only complaint. A past history of a nonpersistent urinary infection, of perinephritis, or of an injury that has been directed to the renal region, may be suggestive. No evidence of infection, stone, tumor or urethral obstruction is discovered. Unless there is marked displacement or very firm adhesion of the kidney below, palpation and roengenography will give normal findings. Mathé[12] has recently reported an instance in which he demonstrated by pyelography that adhesions following perinephritic abscess had anchored the kidney high up in the renal fossa, thus preventing even normal mobility.

I believe the two cases that form the basis of this report will illustrate the importance of an early diagnosis and the beneficial results attending complete removal of the cicatricial investment of the kidney.

The patients were young men. The symptoms of renal compression became severe several years after an apparently successful drainage of a right perinephritic abscess.

Both patients complained of a dull lumbar pain, which was localized and did not radiate to the abdomen, groin or thigh. In each instance the pain was markedly increased when the daily fluid intake exceeded 3 quarts. The pain became acute and sedatives were required when a quart of fluid was taken during a two hour period.

The only objective finding was a deficiency of function on the affected side. There was no evidence of stone, tumor or urinary obstruction, and the ureteropyelograms were normal. This unilateral diminution of renal function was evidenced by a fixed low specific gravity, a lessened excretion of urea, chlorids and total solids, and a retarded phenolsulphonephthalein excretion. In each instance the opposite kidney was normal or slightly more efficient than usual. These divided urine tests were made from two to four times in each instance before operation.

The operative procedure consisted in a complete removal of the cicatricial capsule and a thorough mobilization of the renal pedicle, pelvis and upper ureter.

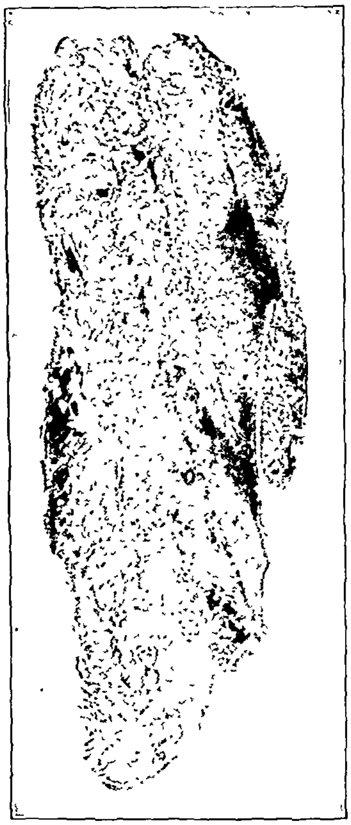

Fig. 1 (Case 1).—Cross section of perirenal scar, showing sclerotic tissue without any gross appearance of contained fat.

The decapsulation, or decortication, was performed with care, as it was necessary to use sharp dissection in removing the scar. Any attempt at stripping the capsule resulted in the tearing out of cortical tissue, which was firmly adherent and in some areas surrounded by the sclerotic tissue.

According to Kolischer, the term "nephrolysis" was introduced by Rovsing to denominate an operation the purpose of which is to free the kidney from pathologic conglutinations and attachments. This term seems more appropriate than decapsulation or decortication.

Thévenot[13] reported a case of sclerous perinephritis developed from an old kidney infection. After "decortication" there was relief from pain, and complete functional efficiency of the kidney was restored.

Nicolich[14] reported a case of fibrolipomatous shell enveloping the kidney, the capsule being adherent to the perinephritic mass and to the kidney. There had been intense lumbar pain for fourteen years. "Decortication" was performed with difficulty, and there was complete cessation of pain.

In one of the ten cases of perinephritic abscess reported by Ockerblad,[15] the fat capsule at operation was found thickened and congested and with many surrounding adhesions. Relief was obtained by removal of the adherent mass.

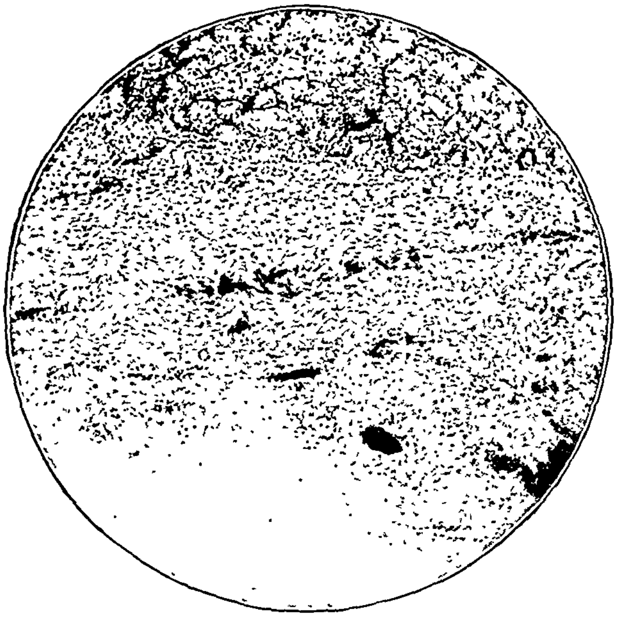

Fig. 2 (Case 1).—Fibrous tissue penetrating the renal cortex, the border of which contains numerous areas of round cell infiltration.

Scheele[16] quotes Lichtenstern as having reported several cases to the German Urologic Congress (1919) in which there were chronic inflammatory changes in the fibrous capsule explaining chronic unilateral pain and which he cured by decapsulation of the kidney.

CASE 1.—A man, aged 34, seen, Jan. 6, 1923, complained of a dull aching pain persistent in the right lumbar region for the past eight months. There was no other complaint. The pain was continuous, did not radiate to the abdomen, groin or thigh and was aggravated by exercise and the drinking of large quantities of fluid. Fifteen years prior to this examination he had a right perinephric abscess following an acute tonsillitis. The abscess was drained, and the patient had no illness of any kind until the onset of this pain, eight months before I saw him. There had never been any unusual urinary symptoms. Tonsillectomy followed the previous operation. Six months before admission he had been subjected to a cystoscopic examination and ureteral catheterization, and pyelograms were made. Following this examination he was told that the urinary organs were normal.

General physical examination, including complete gastrointestinal studies, showed no abnormality except a slight tenderness in the right costovertebral angle. Urine and blood analyses were normal.

January 7, cystoscopic examination revealed a normal bladder, and both ureters were catheterized for a distance of 30 cm. Twenty cubic centimeters of urine obtained in fifteen minutes from the left kidney had a specific gravity of 1.018; 12 c.c. of urine during the same period from the right kidney had a specific gravity of 1.006. Cultures from each kidney were negative. The urine from the left kidney showed two and one-half times the amount of urea and chlorids obtained from the right.

---

[13] Thévenot: Lyon chir. **10**: 23, 1913.

[14] Nicolich: Jour. d'Urol. **4**: 70, 1913.

[15] Ockerblad, N. F.: Perinephritic Abscess as a Urologic Problem, J. A. M. A. **83**: 2074 (Dec. 27) 1924.

[16] Scheele, K.: Klin. Wchnschr. **3**: 841 (May 6) 1924.

Phenolsulphonephthalein injected intravenously appeared from the left kidney in three minutes and from the right in six minutes. Sixteen per cent. of the dye was excreted from the left kidney in fifteen minutes; 8 per cent. from the right.

Ureteropyelograms were clear and were normal in every respect. The kidney shadows were normal in outline.

Divided urine functions were rechecked, January 10 and 16, and approximately the same relative discrepancy was found. At operation through lumbar incision, January 17, the kidney was so adherent to the perirenal tissues, posterior peritoneum and diaphragm that it could not be delivered until the hardened thickened capsule was incised and dissected free from the exposed cortical tissue. In some areas it was necessary to remove small portions of the cortex to continue the enucleation. When this was completed the kidney was delivered, and the pelvis and upper ureter were freed from surrounding adherent hard fatty tissue. The kidney was then restored to its usual position.

Following operation there was complete relief from pain, and June 15, 1924, careful divided functions gave normal and equal excretion on both sides. These findings were corroborated, Jan. 10, 1925.

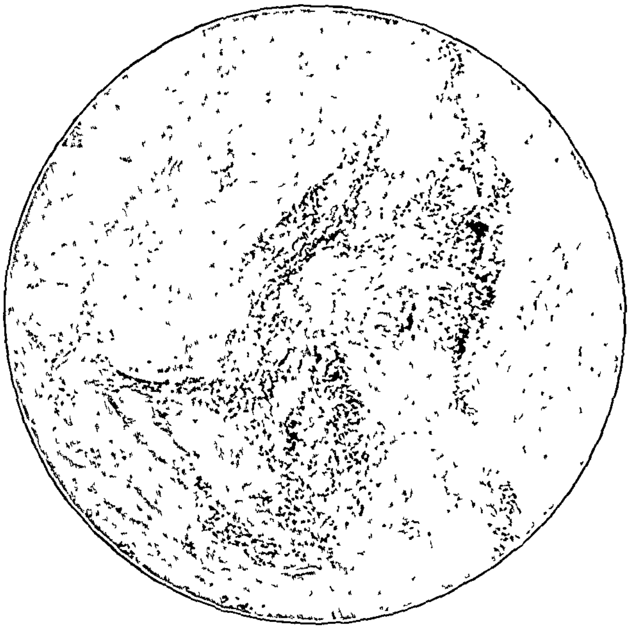

Fig 3 (Case 2).—Sclerotic, fibrous perirenal scar There is no evidence of contained fat in the connective tissue, although there are many areas of round cell infiltration.

Sections of the cicatricial shell showed it to be 3.5 mm. thick and composed of closely arranged fibrous tissue, very hard on incision and with no gross appearance of contained fat (Fig. 1). Microscopically, the connective tissue contained many areas of round cell infiltration with a few closely enmeshed areas of fatty tissue. In some areas the renal cortex was intimately adherent to the fibrous tissue, which penetrated the renal tissue for a distance of 1 mm. (Fig. 2). Along this border there were numerous areas of round cell infiltration.

Case 2.—A man, aged 24, presented himself, Feb. 12, 1923, complaining of a continuous pain in the right lumbar region for the past three years. The discomfort had gradually increased until the patient could no longer endure it The pain was localized, did not radiate and was aggravated by exercise and the drinking of large quantities of fluid Occasionally he was obliged to urinate once at night; otherwise there had never been any urinary symptoms.

Six years before he had a right perinephric abscess without apparent focus for the infection This was drained, and there was no pain for three years. Several roentgenograms failed to show evidence of renal calculus, and since repeated urinalyses were reported normal, he was told by several physicians that he had no kidney disease.

Since he was seen immediately after the patient in the case previously reported, and because his history and complaint were so similar, he was subjected to a careful urologic examination, February 13.

Cystoscopy showed a normal bladder. Both ureters were catheterized 30 cm. Cultures from each kidney were negative. No acid fast bacilli were found; 30 c.c. of urine from the left kidney had a specific gravity of 1.020, and 18 c.c. from the right showed a specific gravity of 1.005. The urine from the left kidney contained twice the quantity of urea and chlorids obtained from the right.

Phenolsulphonephthalein injected intravenously appeared in four minutes from the left and in eight minutes from the right. Twenty per cent. of the dye was excreted from the left kidney in fifteen minutes and only 8 per cent. from the right

Ureteropyelograms were normal, as were the kidney outlines.

Divided urine functions were taken again, February 15 and 18, with the same findings. February 16, the patient was made to drink 1,000 c c. in a two hour period. For three hours subsequent to this the patient had such severe right renal pain that morphin was required to comfort him.

At operation, February 19, the kidney was delivered with some difficulty and was found completely surrounded by a hard, dense, scarlike shell. This was removed by scalpel dissection and was so intimately adherent that in some areas there were portions of cortical tissue cut away with the cicatrix. The ureter and pelvis were not surrounded by hardened fat as in the previous case.

Following operation there was complete cessation of pain, and Oct. 3, 1923, and Dec. 10, 1924, the function of each kidney was found to be normal.

Sections of small portions of the cicatricial capsule showed it to be 2.5 mm. thick and grossly appeared to be hard, fibrous tissue. There was no evidence of retained fat in the connective tissue meshes, although there were many areas of round cell infiltration (Fig. 3).

SUMMARY

1. Perirenal sclerosis, better called "chronic cicatrizing perinephritis," may evidence itself at a considerable period after an acute perirenal infection.
2. The only symptoms may be a persistent pain in the affected kidney and a deficiency of urinary elimination from this organ.
3. Nephrolysis, or decapsulation, relieved all pain in the two patients under discussion, and there was ultimately a complete return to normal function on the affected side.
4. The pathology of this condition represents a replacement of the fibrous and fatty capsules of the kidney by a dense, fibrous cicatricial shell which contains evidence of a persistent low grade interstitial infection. The cicatricial contraction about an otherwise apparently normal kidney must have been the cause of pain and lowered renal function in these two cases.

Surgical Treatment of Habitual Criminals.—It has been shown by statistics collected in the state of Indiana that 100 families have committed more than one half of the crimes done to native-born citizens during the past generation. But this is not all, for the offspring of respectable members of society are constantly exposed to the harmful influence of contact with these degenerate classes and their offspring. Moreover, the lives of the offspring of these unfortunate classes are full of trouble and sorrow from their beginning to their miserable end, and few if any members of these classes do not regret the fact that they were born. . . . If, then, it is possible, by the surgical treatment of these cases, to reduce the number of their progeny, it seems reasonable to advocate this surgical method so that society can be protected against at least a part of the harm it now suffers without harming the individuals who receive this surgical treatment.—Ochsner, A. J.: *Ann. Surg.* **82**:321 (Sept.) 1925.

BLADDER REFLUX

A CLINICAL AND EXPERIMENTAL STUDY *

DANIEL N. EISENDRATH, M.D.
HARRY KATZ, M.D.
AND
JULIUS M. GLASSER, M.D.
CHICAGO

Under normal conditions, the backflow of bladder contents into the upper urinary tract is prevented by a mechanism at the ureterovesical junction which acts like a sphincter. When, as the result of congenital or acquired conditions, this mechanism fails to act, urine from the bladder flows back (reflux) into the ureter and renal pelvis. A recent case has impressed on us the necessity of keeping in mind the possibility of such a reflux in cases of severe renal infection:

A man, aged 50, was referred, on account of a marked urosepsis, by Dr. Vance Rawson. In addition to the history of a spinal syphilis of ten years' standing, complete retention of urine had existed for several weeks. No relief of the infection being obtained from an indwelling catheter, it was deemed advisable to ascertain whether some form of mechanical obstruction at the vesical neck was present. Cystoscopy revealed only marked trabeculization and gaping ureteral orifices. A cystogram (Fig. 1 *A*) showed a unilateral (left) reflux. The renal infection, which later (Fig. 1 *B*) proved to be bilateral, yielded rapidly to the use of the indwelling ureteral catheter, combined with vigorous antisyphilitic treatment. The bladder muscle regained its tone, and the ureterovesical mechanism now functions and cystograms made twelve months later (Fig. 1 *C*) fail to show reflux, and the evidences of the renal infection have entirely disappeared.

In a second, similar case, the reflux was bilateral (Fig. 2), and cystoscopy revealed such marked gaping of the right ureteral orifice that it was at first considered to be the opening of a diverticulum (Fig. 3). This free communication of the upper and lower urinary tracts had existed, however, so long that treatment was of no avail.

Summary of Clinical Observations

Group	Condition	Number of Cases	Reflux in	No Reflux
1	Normal	10	.	10
2	Pregnancy	41	.	41
3	Nonobstructive bladder and prostate lesions	10	3	7
4	Nonoperated bladder neck obstructions	12	.	12
5	Vesical and bladder neck lesions after operation	6	.	6
6	Renal and ureteral lesions before operation	8	2	6
7	Nephrectomy cases after operation	4	.	4
	Totals	91	5 *	86 †

* Equals 5 4 per cent.
† Equals 94.6 per cent.

CLINICAL AND EXPERIMENTAL STUDY OF REFLUX

With the cooperation of Dr. R. A. Arens, roentgenologist to the Michael Reese Hospital, we began a study as to the frequency of reflux under normal and pathologic conditions. Our results are shown in the accompanying table.

The technic in all of these clinical cases was practically the same. The first exposure was made after 5 ounces (150 c.c.) of a 25 per cent. solution of sodium bromid had been injected, and a second one after an additional 3 ounces (90 c.c.). The majority were able to tolerate the larger quantity. Group 1 includes ten patients admitted to the general surgical services for conditions such as fractures of the extremities, or goiter, which were not accompanied by symptoms or demonstrable lesions referable to the urinary tract. In none of these was a reflux found.

Group 2 includes thirty-one cystograms of pregnancy cases previously made by Dr. Julius E. Lackner of the gynecologic department of the Michael Reese Hospital, and ten more recent ones in collaboration with us. The majority were in women in the fourth or fifth, a few in the latter months, of pregnancy. The primary object of the cystography in these cases was to study displacement of the bladder in pregnancy. It also enabled us to observe whether reflux occurred often enough to be a factor in pyelitis of pregnancy. That it does not do so frequently is shown by the negative results in the forty-one cases.

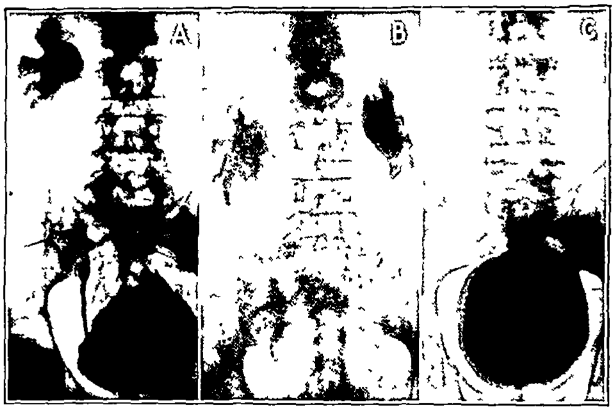

Fig. 1.—Three clinical stages of first case cited: *A*, unilateral reflux complicating atony of bladder; *B*, bilateral hydronephrosis (infected) pyelograms four months after reflux was recognized (*A*); *C*, cystogram one year after observation of reflux seen at *A*, with absence of reflux.

In Group 3 we found a relatively larger percentage of reflux than in any other. The three positive cases were (*a*) in the case cited at beginning of this paper; (*b*) in a case of senile atony of the female bladder complicated by diverticula, and (*c*) in a woman who had tertiary syphilis (Fig. 5 *A*), a well marked cystitis and typical "rigid" ureteral orifices; i. e., did not contract during cystoscopic observation.

In Group 4, one would expect to find a fairly high proportion of reflux. Our negative findings in twelve cases (prostatic adenoma, bladder neck contracture, cancer of prostate, vesical calculi, multiple diverticula, urethral stricture) correspond with those of Bumpus,[1] who found reflux in only 5 per cent. of cystograms from 527 adenomatous prostates.

In Group 5, prostatectomy had been performed in five of the six cases, from two months to two years before. In the other patient we failed to find reflux, although a transvescial diathermy for papillary carcinoma and later a prostatectomy had been done.

Group 6 includes cases of renal infection (nontuberculous and tuberculous), renal and ureteral calculi, etc., with accompanying vesical lesions. Reflux was observed in a case of very advanced bilateral nontuberculous renal infection (Figs. 2 and 3) and one of bilateral renal tuberculosis (Fig. 5 *B*), with apparently few bladder or ureteral orifice changes. The remaining cases (six) were negative, including one of well marked bilateral pyelitis in a girl, aged 8.

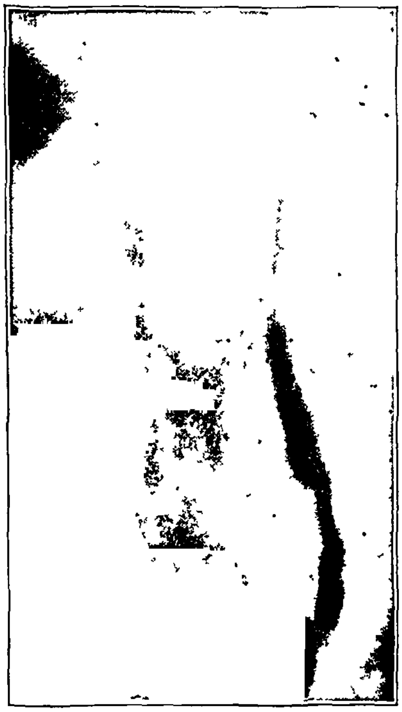

Fig. 2.—Bilateral reflux in case of advanced renal infection (bilateral) of many years' duration, this is to be compared with cystoscopic view of same case (Fig. 3).

We made cystograms in Group 7 because, in a number of recent articles, there are reports of reflux into the ureteral stump after nephrectomy and especially in tuberculosis, into the ureter of the remaining kidney. We failed to find reflux in four cases in which nephrectomy was done for severe nontuberculous renal infection complicating ureteral calculi, or for stricture and hydronephrosis.

ANIMAL AND CADAVER EXPERIMENTS

The question of reflux in rabbits has been so exhaustively studied by Graves and Davidoff,[2] as well as previous investigators, that only a sufficient number of experiments were made to corroborate the frequency with which reflux occurs in rabbits when only relatively small amounts of distending medium and low pressure are employed. We obtained positive results in two of three rabbits (Fig. 6), in both of them unilateral. Graves and Davidoff obtained a reflux in 86.8 per cent. of seventy-six rabbits, and other investigators similar percentages. There have been a much smaller number of reflux experiments on dogs. We have begun a series, but can report only two at present. In one (a large animal) the result was negative, while in a second, much smaller dog, a unilateral reflux appeared when 30 c.c. was injected at 140 mm. of mercury pressure, and a bilateral reflux when this was raised to 40 and 160, respectively. A single cadaver experiment was made. Even when the bladder was tensely filled with the opaque medium, so that the intravesical tension was very high, no sign of reflux appeared, showing that, even independent of any nerve influence, the mechanism at the ureterovesical orifice is effective against reflux.

THEORIES AS TO CAUSATION OF REFLUX

There is still much difference of opinion. Gayet believes that all cases are due to a congenital inability of the lower end of the ureter to oppose the reflux when the bladder wall contracts. This view applies to comparatively few cases, in our opinion. Some favor the theory that a tonic contraction of the bladder on its contents is able to open the ureteral orifices. This does not explain all cases, as will be evident when one recalls the frequency with which reflux occurs when there is a neurogenic or purely muscular atony of the bladder and ureteral walls, as seen in myelitis, spinal syphilis (Fig. 1) and tabes. The negative test for reflux (Fig. 1 *C*) six months and one year, respectively, after appropriate local and general treatment in our first case, would speak in favor of atony of the vesical and ureteral musculature as a not infrequent, and yet remediable, cause of reflex. That either acute or chronic inflammatory changes in the vesical or ureteral wall which interfere with the proper closure of one or both ureteral orifices play a very important part cannot be denied, because reflux is very frequent under these conditions (Groups 3 and 6).

CLINICAL IMPORTANCE AND GROUPING OF REFLUX CASES

There are few statistics, so far, as to the frequency of reflux. In a study of 1,036 cystograms from the Mayo Clinic, Bumpus[1] found reflux in eighty-nine, or 8.59 per cent. It was never found in the normal bladder except in children. The latter corroborates the finding of Kretschmer, who observed reflux in three of ten children under anesthesia.

We believe, from our own work, that reflux occurs so rarely in normal persons as to be a negligible clinical factor. The importance, however, of this comparatively recently known phenomenon, under pathologic conditions, cannot be underestimated. That it plays a part in the spread of infection from the bladder to the kidneys, on the one hand, and from a diseased kidney of one side to the normal opposite one can no longer be denied. In renal tuberculosis, for example, the finding of tubercle bacilli in the urine from both kidneys may lead to an erroneous diagnosis of bilateral disease, unless one has made a cystogram to ascertain whether a reflux on the supposedly normal side is responsible for the findings. Again, the use of irritating solutions

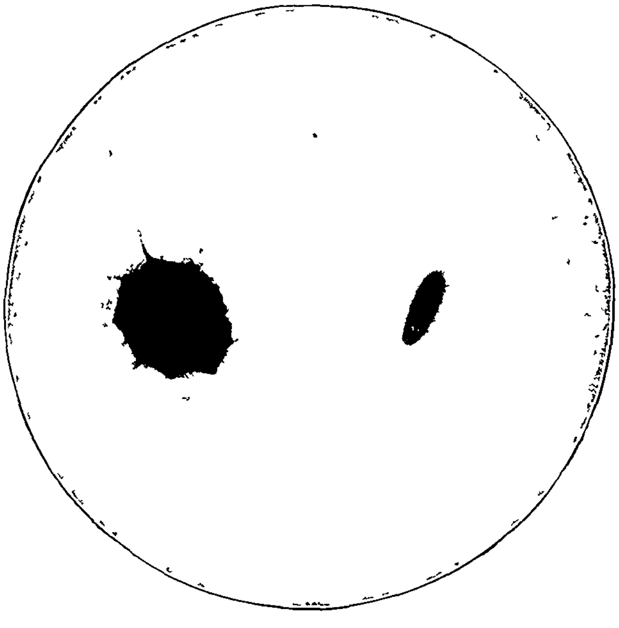

Fig. 3.—Cystoscopic view in case of bilateral renal (advanced) infection complicated by bilateral reflux; gaping of right ureteral orifice resembles appearance of diverticulum

or of too much force in the irrigation of an infected bladder may be followed by acute exacerbations of a preexisting pyelonephritis in the form of chills, fever, etc. Reflux explains why so many cases of pyelitis resist treatment as long as the bladder condition persists.

---

[2] Graves, R. C., and Davidoff, L. M.: J. Urol. **10**: 185 (Sept.) 1923; **12**: 93 (Aug.) 1924.

Helmholtz is of the opinion that reflux is of more importance in the etiology of renal infections in early life than any other factor. For clinical purposes, we may divide reflux into the following groups:

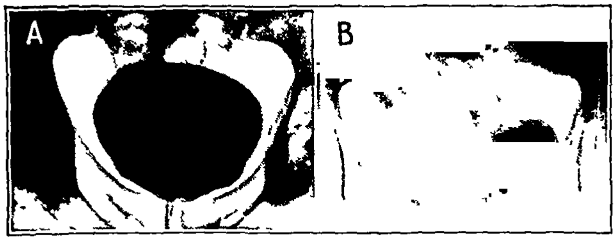

Fig 4 —*A*, cystogram of normal person showing absence of reflux, *B*, cystogram in fifth month of pregnancy; compression of bladder vertex and absence of reflux may be noted

1. Congenital.
2. In severe acute cystitis, especially after introduction of caustic fluids (cases of Gayet, Scheele).
3. In chronic nontuberculous infections of the entire urinary tract.
4. In genito-urinary tuberculosis.
5. In mechanical obstruction at the bladder outlet.
6. Cases of neurologic origin (spinal injuries, myelitis, spinal syphilis, tabes).

The recognition of reflux without a cystogram is very difficult. One can suspect such a condition if there is pain over one or both kidneys after micturition, or if the ureteral orifices appear rigid or gape considerably (Fig. 3). If signs of acute pyelitis appear after irritating solutions have been employed for vesical lavage, or too much force is used in injecting them, the possibility of a reflux being responsible should be borne in mind.

Cystography is a simple and harmless procedure and will probably soon become a portion of the routine examination of urologic cases and add much to our knowledge of reflux.

SUMMARY AND CONCLUSIONS

1. By bladder reflux is to be understood the regurgitation (backflow) of bladder contents into the ureters and renal pelves.

2. The condition may be congenital or develop in postnatal life. That it is not a permanent affection is shown by the first case reported, in which a marked reflux complicating atony of the bladder and due to spinal syphilis entirely disappeared after appropriate local and general treatment.

3. Reflux plays an important part in carrying the infection from the lower to the upper urinary tract and explains the recurrence and resistance to treatment in such cases.

4. It may lead to an erroneous diagnosis of bilateral renal tuberculosis because it is a frequent complication of that disease.

5. It is extremely rare in normal persons and during pregnancy. Acute and chronic cystitis favor it because of changes in the lower ureter preventing proper closure of the orifice on one or both sides.

6. In ninety-one cases including normal persons, pregnancies and various vesical and renal conditions, reflux was found in only five, or 5.4 per cent., most frequently in infections of the bladder and kidney, both tuberculous and nontuberculous. Obstruction at the vesical neck is a comparatively rare cause of reflux.

7. There is still much difference of opinion as to the reason why the mechanism at the ureterovesical junction, which normally opposes the reflux of bladder contents, should fail to function. Some hold that a hypertonic vesical musculature forces the ureteral orifices open. Some believe that a congenital insufficiency will explain all cases. A third group holds that changes in the wall of the lowermost portion of the ureter from lack of innervation or disease prevent the proper closure of the orifices. One must concede that all three of these may coexist, or even, acting alone, be sufficient cause for the phenomenon.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. O'CONOR AND OF DRS. EISENDRATH, KATZ AND GLASSER

Dr. R. C. Graves, Boston: Regurgitation into the ureters has interested me intensively for several years. The important bearing of reflux on the problem of ascending urinary tract infection led us into investigations which might prove or disprove the occurrence of this phenomenon. The evidence to date, and it has been strongly confirmatory evidence, has been chiefly experimental. We now need every possible clinical contribution that may throw light on the problem and enable us to value better the laboratory facts. In the first place, I am impressed by the need for exact definition of reflux. The word regurgitation denotes in this case an active process in which the bladder, actively contracting in the presence of obstruction, forces its fluid back into the ureters instead of through the normal outlet. Furthermore, to be significant, reflux must occur before the normal ureterovesical mechanism has been broken down. There is no question involved in the familiar passive back-wash from bladder to kidney through patulous ureters which have been dilated as the result of chronic disease. In such cases the cystograms

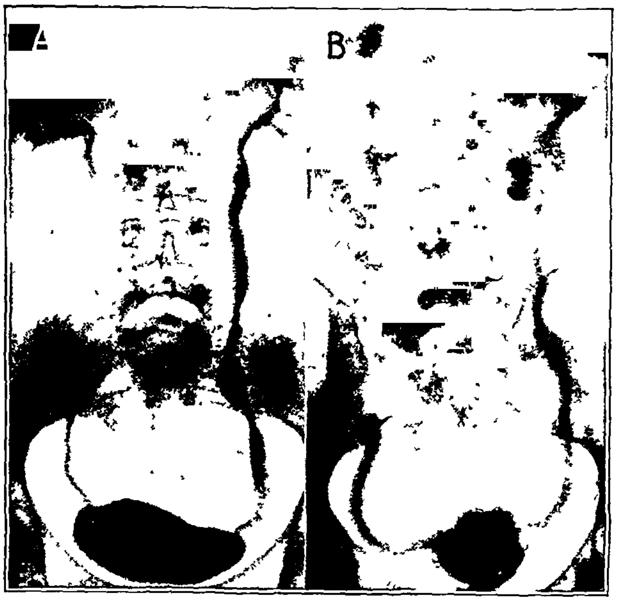

Fig 5 —*A*, bilateral reflux in woman aged 30, with tertiary syphilis; *B*, bilateral reflux in man, aged 30, with bilateral renal tuberculosis.

will of course show ureteral filling. The experimental problem has involved the possibility of reflux through intact orifices, and the clinical question, if there is to be any analogy, must be approached on the same basis. I think further, that it is unsafe to draw clinical conclusions on the basis of cystograms alone. Regurgitation may be very fleeting, and only a small amount of bladder fluid may escape into the ureters. The film or two films account for but a small fraction of the total time of bladder filling, and absence of reflux in the plate is not proof that it has not occurred, or that it might not occur with further distention. Again, may I suggest that we should be more concerned in this study with pressures within the bladder. Regurgitation occurs in the presence of active pressure produced by active sustained resistance to distention on the part of the bladder musculature. Cadaver experiments are futile. It is necessary to know much more than the amount of fluid injected before we can accept a given case as adequate evidence for or against reflux. In our laboratory study, which was carried out purely as a basis for the clinical study of regurgitation, we observed reflux in more than 80 per cent. of a large series of normal rabbits under as nearly normal conditions as experimentation will permit. There was no disturbance of innervation in these cases. In the normal cat and dog groups, reflux was observed in 62 per cent of the former and 27 per cent. of the latter. The lesser incidence in dogs is not due to difference in anatomy but rather to different physiologic reaction to distention on the part of the bladder muscle in these animals. There can be no question concerning the experimental occurrence of regurgitation into normal ureters in normal animals. The clinical application of this evidence is still to be completed; but I am convinced, on the basis of our studies, that reflux occurs in the human being in the presence of vesical neck obstruction.

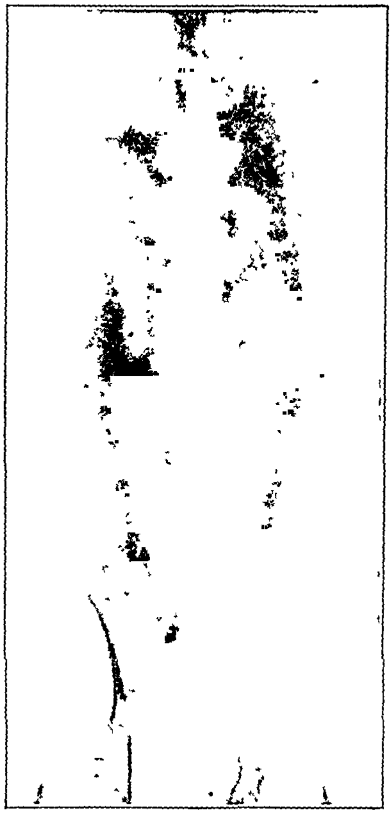

Fig 6—Unilateral reflux in rabbit.

Dr. Paul W. Aschner, New York: In cortical abscess and carbuncle of the kidney, absorption of the perirenal fat is observed at the time we operate It is a good plan not only to open and drain the particular abscess we are dealing with, but also to decapsulate the kidney to favor the breaking through of other abscesses that may be present in the parenchyma. The paper of Dr. Eisendrath is of much interest. A number of years ago the condition of ureterohydronephrosis in children was brought to our attention and studied in Dr. Beer's clinic. Cystograms showed huge dilated ureters (bladder reflux or regurgitation). Some cases treated on the basis of contracture of the vesical neck have had an excellent postoperative result. I think it will be instructive to get these children back to see whether the reflux has disappeared. The importance of possible reflux during cystoscopic examination in cases of renal tuberculosis cannot be overemphasized, for undoubtedly cases of bilateral involvement reported in the literature as cured after nephrectomy on the worse side were errors in diagnosis occasioned by reflux. It is most important to determine that no reflux is present when collecting ureteral specimens. We should make it a practice to keep the bladder continuously empty during this procedure. A good way to determine clinically whether there is a reflux or not is to put an ounce or two of indigocarmin into the bladder continuing the ureteral drainage. If there is no dye in the ureteral specimens, one may be sure that there has been no reflux. I have seen reflux follow nephrectomy. On one occasion the patient was reported to be voiding no urine at all, and we found that the ureter stump had opened and the urine was passing out of the lumbar wound. We have seen reflux in children and in adults with atonic and incompetent bladders. Whether it occurs after prostatectomy is important. Some patients after prostatectomy will begin to void small amounts, will suddenly stop draining through the wound, and will then void many ounces at one time. This may be immediately followed by chill and fever and renal tenderness. I think it is possible when we enucleate the adenomatous prostate to liberate the interureteral ridge and trigon, separating it from its normal connections with the rest of the bladder so that reflux can occur. Recently I treated a man with an old spinal cord injury. As soon as 5 or 6 ounces of water had been introduced into the bladder by the cystoscope, he complained of pain in both kidney regions. We did not make a cystogram because we found he had typhoid and did not wish to do anything more for the present. In a man with contracture of the vesical neck, whose right kidney has been removed, fluoroscopy was done while the iodid was being injected. After 3 ounces had entered the bladder, the latter was seen to contract and the left ureter suddenly filled with the solution.

Dr. Herman L. Kretschmer, Chicago: Dr. O'Conor's paper calls attention to the fact that the persistence of pain after draining a perinephritic abscess may be due to a perirenal sclerosis and is not, as is often assumed, due to adhesions. It seems to me that he has shown rather graphically that the pain is due to something more than adhesions. Patients with a perinephritic abscess may have a definite fibrosis around the kidney, and the persistence of pain after a perinephritic abscess has been drained, is highly suggestive of perirenal fibrosis or sclerosis. On the other hand, in the cases in which there is no history of a perinephritic abscess it is difficult to make this diagnosis. Perhaps, too, we do not think of the possibility of perirenal sclerosis. The results of the examinations and functional tests often do not lend much aid in making the diagnosis. Dr. Aschner called attention to the enormous amount of perirenal sclerosis that is found with so-called carbuncle of the kidney, and I believe that in this lesion one finds the greatest amount of perirenal fibrosis. Regarding Dr. Eisendrath's paper on regurgitation: This always opens up a very interesting subject on the physiology of the ureter. Lewin and Goldschmidt in Germany, and Guyon and Courtade in France reported on this work many years ago. And in this country O'Conor and Graves have published their researches recently. That reflux is a possibility, I was able to prove in 1916. I have seen reflux in all sorts of pathologic conditions, as Dr. Eisendrath has mentioned. I saw it once in a case of abscess of the prostate, and several times in patients who had benign papillomas of the bladder. Dr. Eisendrath mentioned the fact that reflux is not constant, and I found it to be so. If it is not present at one time it does not mean that it never occurs. Regarding reflux in renal tuberculosis, I, too, have seen cases in which all the urine was voided from the side from which a tuberculous kidney had been removed; that is, through the wound in the loin. Reflux has served us well in two or three instances in which we were unable to find one of the two ureters at cystoscopic examination in cases of renal tuberculosis. We made cystograms and found regurgitation of fluid on both sides with pathologic changes present on both sides. Dr. Young, as we all know, carried out his experiments under hydrostatic pressure, injecting fluid into the bladder. He tried to get it to back up the ureters but could not get it to do so. This work was done on cadavers. I think this entire subject should be considered from two standpoints: first, as a congenital insufficiency of the ureterovesical valve, not a case of reflux, and second, when ureterovesical valves are perfectly normal and fluid regurgitates up the ureter.

Dr. Ralph L. Dourmashkin, New York: The amount of the opaque solution that Dr. Eisendrath uses in doing his cystograms, I believe, is too excessive. There is always a potential danger in doing a double pyelogram, and those who are against doing it at the same sitting will agree with me. I know of one case in which death followed a cystography. The patient was a boy, aged 5. The house physician was instructed to make a cystogram. He injected 4 or 5 ounces of the opaque solution, and the boy died on the following day. The roentgen ray showed a bilateral reflux into the pelves of the kidneys. I think it is possible to get a perfect outline of the bladder and even a reflux with as little as from 50 to 75 c.c. of the solution.

Dr. Robert H. Herbst, Chicago: I have seen two cases that illustrate the part played by the muscular coat of the bladder in both the prevention and the production of reflux. The first case was one of active incontinence with a contracted bladder and marked hypertrophy of the bladder wall. There was an obstruction in the left ureter about 10 cm. from the orifice. With the patient on the fluoroscopic table and contrast fluid injected into the left ureteral catheter, the fluid could be seen flowing back into the bladder, when it would be promptly forced up the right ureter to the kidney pelvis. The second case was one of fistula between the sigmoid and the bladder. Contrast fluid injected into the bladder could not be forced into the bowel because of the action of the muscular coat of the bladder, closing the vesical end of the fistula. This is found in nearly all cases of fistula between bowel and bladder except those located on the posterior wall near the neck. Under normal conditions the muscular coat plays an important rôle in the prevention of reflux, and where the innervation is disturbed it may have much to do in the production of it.

Dr. Vincent J. O'Conor, Chicago: The points that I wished to bring out in this paper regarding chronic, cicatrizing perirenal sclerosis were, first, that the process probably occurs more frequently than is generally recognized. I know that in the past I have seen patients with a so-called nephralgia who had been classified as neurotics, in whom nothing was found on careful examination and who had been dismissed without treatment. Secondly, I wish to stress the fact that conservatism in these cases, when they are recognized early, is worth while. The removal of the constricting shell from a kidney of only one-half function will permit a return to practically normal function after a time. Regarding the passage of material from the bladder and ureters to the kidney; there is a great deal of confusion on the part of some men regarding this phenomenon. There are two distinct mechanisms which produce regurgitation and reflux. Under the stimulation of Dr. Quinby we studied this condition experimentally, and Dr. Graves has elaborated on these findings by further experimental and clinical work. Reflux from bladder to ureter is not new nor is the phenomenon particularly interesting. It is purely the passage of fluid from the bladder to the upper urinary tract by direct continuity. This is effected by loss of bladder and ureteral muscle tone as occurs in spinal cord disease or injury or prolonged back pressure from bladder neck obstruction. In addition, the stiffening of these structures by chronic infection, notably tuberculosis, results in reflux. Regurgitation is the term used to denote the passage of bladder content to ureter or kidney when the bladder and ureteral muscle tone is obviously normal. The relationship of this mechanism to ascending renal infection is the only point of interest in this work. The cases cited by Dr. Eisendrath are those of reflux and not regurgitation, and do not bring out any points of new clinical interest. In my opinion, antisyphilitic treatment brought about a return to normal muscle tone, which in turn prevented reflux in the cases cited by him. We frequently see the same result in eliminating residual urine in the bladder by active systemic treatment when all local treatment has been avoided.

Dr. Daniel N. Eisendrath, Chicago: I do not feel that one should speak of reflux when ureteral catheters are in situ. In reply to the point raised by Dr. O'Conor regarding the inconstant occurrence of reflux, I would say that reflux was absent six and again twelve months after it had been first observed in the case in which a spinal syphilis led to bladder atony. From a clinical standpoint one cannot differentiate reflux from regurgitation, as Drs. O'Conor and Graves suggest. They suggest that the term reflux be limited to those cases in which the ureteral orifices are intact and the term regurgitation be applied to those in which they gape so that there is a free communication between the bladder and ureter (also renal pelvis). We have not seen any difference in the phenomenon in cases in which the ureters were apparently intact so far as cystoscopy revealed from the reflux in cases in which the ureters gaped widely. From a practical standpoint we are concerned with the question of how we can gain control of the renal infection through our efforts to combat the bladder condition whether the latter be of local or systemic (neurogenic) origin.

ROENTGEN-RAY DIAGNOSIS AND TREATMENT OF THYMOMA

REPORT OF TWO CASES *

T. A. GROOVER, M.D.
A. C. CHRISTIE, M.D.; E. A. MERRITT, M.D.
AND
F. O. COE, M.D.
WASHINGTON, D. C.

To differentiate and determine the source of origin of primary mediastinal neoplasms and other mediastinal masses is notoriously difficult ante mortem, and is at times impossible even at necropsy. This is particularly true both from a roentgenologic and from a clinical standpoint when the patient is first seen after a neoplasm has extensively invaded surrounding structures or pleural effusion has occurred. In the latter instance, the character of the exudate may afford a clue as to the nature of the disease, but its source of origin is apt to remain shrouded in obscurity.

Tumors of the thymus are undoubtedly rare, but their occurrence is probably more common than the reports in the literature would indicate. They are rarely recognized as such during life. If the presence of Hassall's corpuscles is taken as a criterion for establishing the thymic origin of a tumor, even some of the reported postmortem diagnoses are open to question.

The cases reported here present roentgenologic pictures sufficiently characteristic to establish a diagnosis of thymoma with reasonable certainty, and are presented mainly for the purpose of calling attention to these characteristics, and incidentally to illustrate the effects of roentgen rays on this type of tumor.

REPORT OF CASES

Case 1.—Mrs. W., aged 39, white, was referred for roentgen-ray examination, Sept. 2, 1924, by Dr. Howard Fletcher, who suspected the presence of a mediastinal growth. Her history, prior to the beginning of the present illness six months before, was unimportant. At that time she began to have difficulty in breathing, followed later by swelling of the neck, face and hands, and pruritus about the upper part of the thorax. The sense of suffocation and also the swelling were most marked when she was recumbent, and were partially relieved on her assuming an erect posture. The symptoms had become progressively more pronounced, but she did not think she had lost weight. At the time she presented herself, her breathing was of the asthmatic type, and there was marked swelling of the face, neck and upper extremities, together with marked engorgement of the veins, indicative of pressure on the vena cava. There was a marked increase in the mediastinal dulness. Roentgen-ray examination showed the presence of a mass in the anterior mediastinum extending from the third to the eleventh dorsal vertebra and having a transverse diameter of 8½ inches. It was in close contact with the anterior thoracic wall and was nonpulsating. It was circular and extended about an equal distance to either side of the midline. When viewed laterally it was seen to be flattened anteroposteriorly, and apparently not more than an inch thick. The borders were sharply defined and the shape reminded one of a generous sized pancake. The heart and great vessels appeared normal, and there was no evidence that the growth invaded the lungs or pleurae.

---

* Read before the meeting on radiology in the Section on Miscellaneous Topics at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

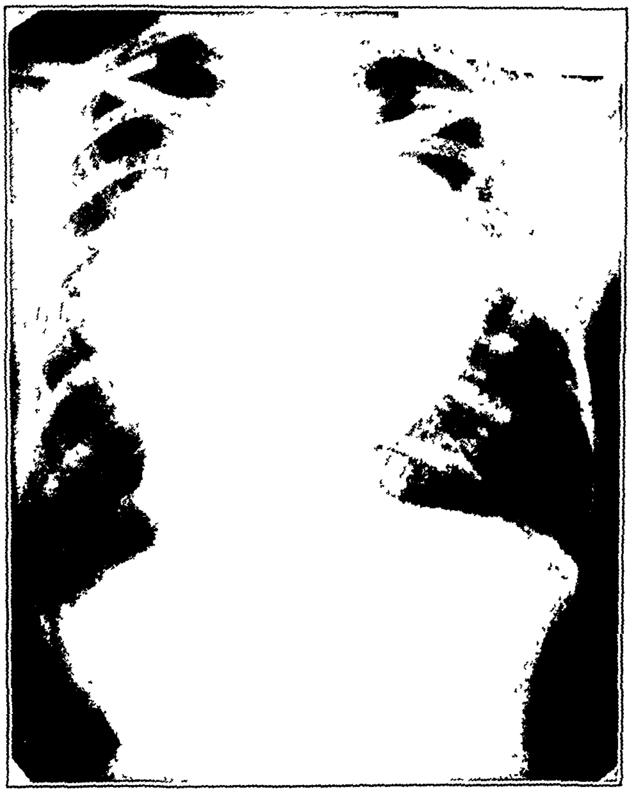

Fig. 1 (Case 1).—Roentgen-ray appearance, Aug. 26, 1924.

Roentgen-ray therapy was begun immediately, and a total of 800 milliampere minutes at 200,000 volts and 50 cm. distance with 0 5 mm. copper filtration was administered in the course of four days. Half this dose was administered through the front of the chest and half through the back.

In two weeks, practically all symptoms had disappeared. The swelling and varicosity of the veins had vanished and the mediastinal mass was reduced about 50 per cent in size. The mass continued to recede, and in two months the chest appeared practically normal. She received further roentgen-ray treatments of the chest in October and December, 1924.

She remained in fairly good condition until January, 1925, when she began to have sore throat. The left fauces became edematous, and ulceration involving the anterior pillar and tonsil rapidly supervened. The ulcer had ragged edges and a grayish necrotic base. The appearance was not unlike that of a primary carcinoma of the tonsil, but it was regarded as being most likely a counterpart of the mediastinal growth. Smears for Vincent's angina and the Wassermann reaction were both negative, and the differential blood count showed nothing characteristic or suggestive. (In this connection it is noteworthy that Friedlander and Foot[1] report a case of malignant small celled thymoma with acute lymphoid leukemia, in which a gangrenous stomatitis with extension to the tonsil occurred.)

At about this time the mediastinal mass reappeared, but had not reached a sufficient size to cause pressure symptoms. Radium needles were implanted in the tonsil, and further roentgen-ray treatment was given over the chest. The throat lesion has entirely disappeared and the mediastinal mass has again undergone marked regression, but has not entirely disappeared. The outlook for a permanent recovery is not considered very encouraging.

Case 2.—E., a white man, aged 61, consulted us, Dec. 5, 1924, with no facts in his previous history that seemed to have any bearing on his present complaints. For four or five years he had had some dyspnea on exertion, but it was very slight and he had paid no attention to it. In 1923, he was operated on for a benign hypertrophy of the prostate from which he made a satisfactory recovery. He had led an active life and considered his health to have been good. About two months before he began to have dull aching pains in his left chest and in his arms. The pain was worse in the left arm than in the right, and the pain in the chest was located above and to the left of the precordium. Dyspnea had increased. The pain in the chest and arms was aggravated by exertion. Two weeks before he had consulted Dr. Merrill M. Myers of Des Moines, Iowa, who made a general diagnostic survey, and at that time a roentgen-ray examination by Dr. Thomas A. Burcham disclosed the presence of a mediastinal mass which he considered to be either an aneurysm or a new growth. A few days later he was examined at the Mayo Clinic, where a diagnosis of a large malignant mediastinal tumor was made. Aside from the roentgen-ray disclosure of a mediastinal mass, other laboratory findings and the physical examination were essentially negative.

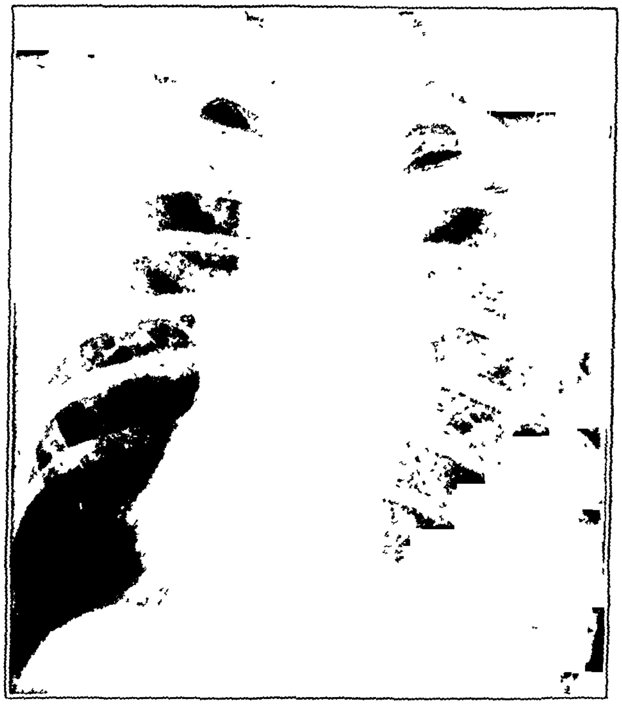

Fig. 2 (Case 1).—Roentgen-ray appearance, Dec. 12, 1924: almost complete disappearance of the mediastinal mass.

The roentgen-ray picture as it presented itself to us was essentially the same as that of Case 1, except that the growth was somewhat smaller. There was a circular, sharply defined flattened mass in the anterior mediastinum, in intimate relation with the anterior wall of the thorax, which did not pulsate and which did not appear to invade the surrounding organs.

Roentgen-ray treatment was begun at once, with an exposure of 800 milliampere minutes made through the front of the chest and a like amount through the back. The exposures were distributed over a period of twelve days. The other factors employed were a potential of 200,000 volts, with a 60 cm. skin focus distance, and 1 mm. of copper for filtration.

[1] Friedlander, A., and Foot, N. C.: Report of a Case of Malignant Small-Celled Thymoma with Acute Lymphoid Leukemia, Am. J. M. Sc. **164**: 161-176 (Feb) 1925.

Within a month, the tumor mass and all of the symptoms had disappeared, and to date have not recurred.

COMMENT

The presence of a circular, sharply defined, flattened, nonpulsating mass in the anterior mediastinum, which hugs closely the anterior wall of the thorax, and has not invaded surrounding organs, justifies, in the absence of other evidence to the contrary, a tentative diagnosis of thymoma.

The peculiar flattening of the tumor and its symmetrical spread is probably due mainly to mechanical causes incident to its location between fairly unyielding structures.

Although it is a characteristic of thymomas that they vary greatly in their histologic structure, it would in general be anticipated that they would respond to radiation therapy in a manner analogous to that of other tumors originating in lymphoid tissues, and that a cure might reasonably be expected in the more benign types, especially if the treatment is instituted early.

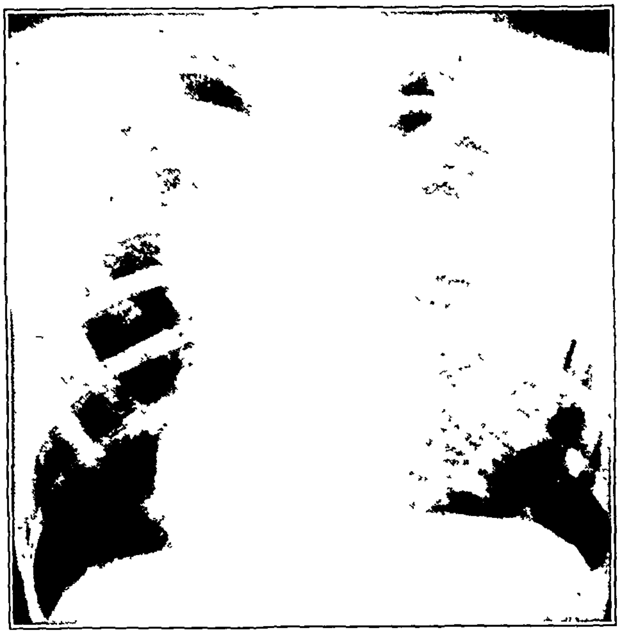

Fig. 3 (Case 1).—Roentgen ray appearance, Feb. 9, 1925, showing recrudescence of the mediastinal mass.

The therapeutic response of mediastinal masses to radiation therapy may also be of great assistance in making a differential diagnosis, and in doubtful cases such a test is fully justified.

ABSTRACT OF DISCUSSION

Dr. Henry K. Pancoast, Philadelphia: Thymic tumors are undoubtedly unusual in the experience of all of us. Probably they are more frequent than we realize, because most of them have not been reported. Many of them have been mistaken for other tumors of the mediastinum. They have, as Dr. Groover has shown, a very characteristic appearance. They are flat, look thin, and do not cast a very dense shadow, and their most characteristic appearance is noted in the lateral view. I was rather surprised to see the low position of both these tumors shown by Dr. Groover. I should expect a tumor originating in thymic tissue to extend well up to the neck. The latter of the two certainly was far away from the neck and was more in the central portion of the chest. So far as I can recall, I myself have seen only one tumor of this kind in a child, and that was many years ago when we were using a low voltage machine and had to treat through small areas. The child died before the treatment could be terminated. Clinically, one would expect dyspnea to be a very prominent symptom, if one gages the symptomatology at all by that of enlarged thymus in the child. The obstruction to the venous return would also be rather prominent, I should think. Of course, the treatment is practically that of a lymphosarcoma, or possibly Hodgkin's disease, although Hodgkin's disease very often requires much less treatment than does lymphosarcoma.

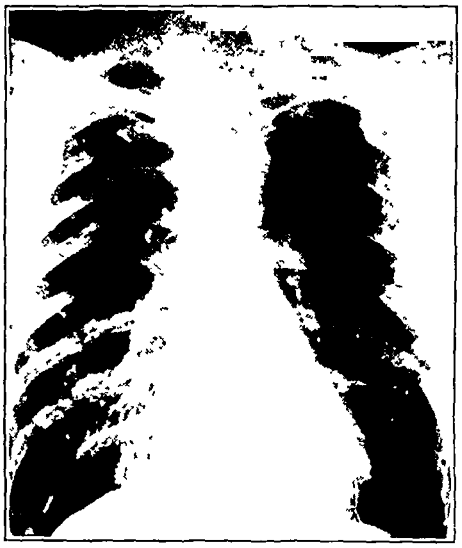

Fig. 5 (Case 2).—Roentgen ray appearance, April 13, 1925, showing complete disappearance of the mediastinal mass. (Courtesy of Dr. Burcham.)

Dr. M. M. Myers, Des Moines, Iowa: I am not a radiologist, but Dr. Groover has asked me to say a word about the second patient, since I was one of the first physicians he consulted following the beginning of his illness. He is a resident of southern Iowa, a lawyer, a member of Congress in Washington, and was referred to me because of the possibility of heart disease. The symptoms were comparatively few, chiefly fatigue and a pain in the left arm. On examination, one noted a pulsation in the second left intercostal space, about 7 centimeters to the left of the midline. This suggested to me the diagnosis of aortic aneurysm. As the author has said, he was referred to Dr. Thomas Burcham for roentgen-ray study, but the picture was so unusual that we admitted that we did not know positively what the condition was. Later he was sent to Dr. Groover. I have seen this patient within the last month, and as far as we can tell, his condition is satisfactory. There is no glandular enlargement to be detected, he is working, and he feels that he is in good health.

EPITHELIOMA OF THE LACRIMAL SAC *

RALPH A. FENTON, M.D.
PORTLAND, ORE.

True neoplasms of the lacrimal sac are somewhat unusual. Many reported tumors are granulomatous or degenerative products of long standing inflammation, while others arise intrinsically from various elements in the sac wall.

The following cases of true epithelioma are noted in recent literature:

Guibert[1] (in 1905), mentioned a limited epithelioma in which cure was effected by the roentgen ray, and following him Rollet[2] and Lafon[3] reported cases of primary epithelioma of the sac, the latter recurrent. Bistis[4] reported a primary cancer in a man of 60, in which the sac wall became 1 cm. thick. Many of the cases reported have come from Italian clinics, and De Vincentiis,[5] as long ago as 1877, pointed out the danger of confusion in diagnosis with ordinary thickening of the sac wall in a chronic dacryocystitis. Maggi,[6] Pasetti,[7] and Denti[8] have contributed several cases. Hermann[9] reports a hard papilloma of the sac. Juler[10] discovered a similar good sized growth in the upper canaliculus. Posey's[11] case was a primary epithelioma of the sac proper.

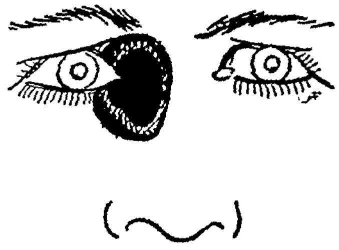

Fig. 1.—Black, extent of tumor; outer shaded area, limit of incision.

These cases were primary tumors, many being benign papillomas, filling the lumen of the sac, which can readily be peeled away from the growth. A few cases showed extensive thickening of the wall, with heaping up of many layers of cylindric and cuboidal cells, readily distinguishable from the hyaline distention of the plasmoma reported by Verhoeff and Derby.[12] The verrucous growths showed marked squamous cell increase, with dipping in and karyokinetic exaggeration in those cases bordering on malignancy.

Radical measures involving the sac have long been a necessary part of the cure of rodent ulcer. Of indirect interest with regard to the case that I shall cite is that of Morestin,[13] wherein radiotherapy had failed. Sac extirpation, with transplantation of a forehead flap, brought a good result. Posey[14] also reports an excellent result from a forehead flap after removal of a very large carcinoma, including much of the upper lid.

An element distinctly unusual enters into the case here reported; namely, the invasion of the normal lacrimal sac structures by a slowly growing epithelioma of the nasal skin, under the stimulating influence of roentgen-ray irradiation.

REPORT OF CASE

M. R. M., a widow, aged 49, was first treated for an intractable roughening of the nasal skin near the inner canthus of the left eye about sixteen years ago. Various dermatologists employed pastes and later began short and frequent roentgen-ray exposures. Such treatment at intervals during some years seemed to destroy the original site of trouble, but the lesion advanced across the bridge of the nose, leaving an unwholesome papyraceous skin behind. This closely resembled that seen after roentgen-ray burns elsewhere. There was no evidence of syphilis or tuberculosis. Repeated short exposures to an unscreened radium applicator were made four years ago, after which the first lacrimal swelling was noted.

Three and one-half years ago the patient became alarmed regarding a hard swelling at the inner canthus of the right eye, and consulted Dr. T. W. Ross. Surface plaques of radium (10 mg. with 1.23 mm. brass screen) were effective in stopping pain and clearing redness and roughness of the skin; but the swelling increased about the sac.

My examination, at the request of Dr. Ross, Jan. 17, 1922, disclosed a smooth, hard, slightly tender swelling, including both the canaliculi and the lacrimal sac. The neighboring conjunctiva was reddened; epiphora was constant. The puncta were normal in size, but no lumen was permeable to delicate probing. Force was not used. External rotation of the globe was somewhat painful.

Radical excision of the growth with as much neighboring skin and periosteum as possible was made, January 20 (Fig. 1). Under gas-ether anesthesia, the inner third of both lids, the skin and periosteum of the lateral aspect of the nose, the lacrimal sac as far down the nasal duct as possible, both canaliculi and the caruncle were removed. The resulting circular defect left one-third the cornea bare, and measured 3.5 cm. in diameter. Three 10 mg. radium needles, in a narrow, hard rubber uterine applicator, were stood upright in the nasal duct, remaining seven hours, 210 milligram-hours in all. Slight tingling for forty-eight hours was the only reaction, and the eye remained clean, under instillation of mercurochrome-220 soluble, 2 per cent., for two weeks. Normal drainage through the nasal duct occurred within a week after the operation, and it has never been occluded since.

Dr. R. L. Benson, head of the department of pathology, examined the tissue removed, which showed obliteration of the lumen of the sac and canaliculi. Microscopically, there was an irregular mass of stratified, squamous epithelium showing evidences of rapid growth. The malignant infiltration extended from the tissue about the eye along the wall

of the tear sac. The pathologic diagnosis was squamous cell carcinoma, highly malignant (Figs. 2 and 3).

Six weeks after excision, the first plastic operation was done (Fig. 4) under procain. A canthoplasty 15 mm. long was lined by loosened conjunctiva, and a crescentic incision over the malar bone was puckered into a Y, to give fulness permitting the lengthened lid stumps to move over toward the nose. The nasal ends of the lids were temporarily sutured together, and anchored by mattress traction sutures to the nasal bridge and forehead.

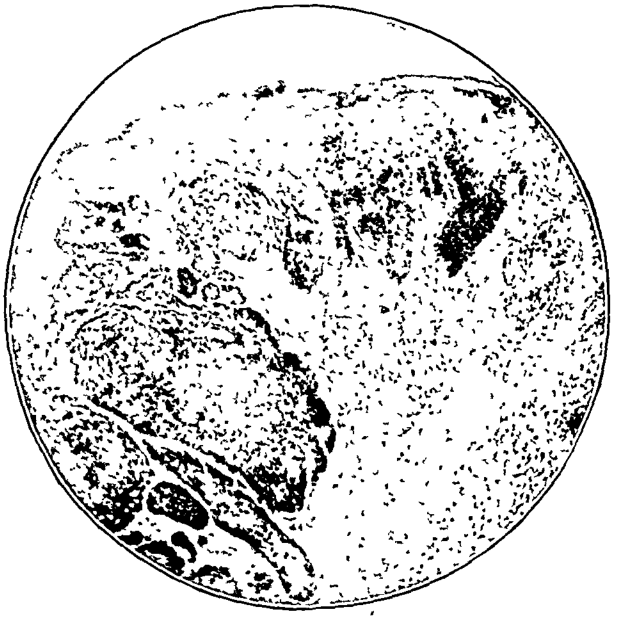

Fig 2.—Normal sac epithelium at top of section, at left and below, invasion by dipping down of cancerous masses

Three months after excision, the opening had been reduced to 15 mm., and a second plastic graft was made under procain (Fig. 5). A rectangular flap, 25 by 35 mm., based at the glabella, was switched from above the unshaven right eyebrow to fill the defect. The distal 5 mm. of this flap was folded under to form a new lid margin. The eyebrow was lifted into the forehead defect. All stitches held except one at the restored inner canthus, which cut out from the softened skin previously damaged by radiation. The cosmetic result was reasonably good (Fig. 6), in view of the extensive sacrifice of tissue. The eye whitened out, and the new upper lid opened and closed accurately. Scarring about the region of the internal rectus interfered somewhat with extreme abduction.

However, ten months after the excision, the patient became aware of an enlargement and hardening of the skin flap; the eye again became red and painful. She was not able to leave her home in a remote district to come in for further radium treatment as advised until twenty months after the original excision and seventeen months after the flap plastic operation (Sept. 26, 1924). A smooth, hard mass 1.5 cm. in diameter bulged up the flap, fixing it firmly to the lacrimal bone and inhibiting abduction beyond 10 degrees. The conjunctiva was slightly reddened; but the nasal duct remained wide open, and there was no sign of recurrence, ulceration or glandular swelling elsewhere.

No further surgical work was considered, and one powerful application of radium was made (220 milligram-hours); she returned three and again four months later, when a total of 840 milligram-hours was administered. The eye has again whitened, and the growth, though still hard, is smaller by one third. Abduction is still limited and painful. At present (February, 1925), three years after excision, the recurrence remains stationary.

CONCLUSIONS

Epithelioma of the skin about the eye may be metamorphosed by stimulant doses of roentgen rays or radium into a type that will invade conjunctival and mucosal structures.

Irradiated papyraceous skin may give rise to epitheliomatous invasion of healthy skin flaps about the eye, at a point of suture or of contact with the moving globe. Such attack is probably activated by irritation of granulation tissue by lacrimal secretion and by the bacterial flora of the skin and conjunctiva.

Radium and the roentgen ray must be used in sufficient strength to produce endarteritis and starvation changes, if employed at all on ocular neoplasms. It is regrettable that no opportunity was afforded for follow-up use of radium in this case.

Caution should be exercised in the selection of a physician for roentgenologic or radiologic treatment about the eye. Commercial exploitation of the sale of apparatus and of radium has brought about the installation of these powerful agents in the hands of physicians untrained in their use; or even into the control of lay technicians, or of so-called beauty specialists. The caution of such guesswork operators, in attempting radiotherapy, is often, as in this case, productive of stimulative changes rather than of destruction. Dermatology and ophthalmology must join hands in deciding methods of screening, distance, intensity and time limits for this valuable, yet highly dangerous, agent.

ABSTRACT OF DISCUSSION

DR. ALLEN GREENWOOD, Boston: It falls to the lot of few ophthalmologists to see a case of primary epithelioma of the lacrimal sac, only a few such having been reported in the literature. In this country Dr. Posey has described a case of primary epithelioma sac, and given a survey of the literature. Dr. Fenton has opened up the general subject so as to cover both the primary cases and those due to extension from some other neighboring structures. Dr. Fenton's case comes under the latter class rather than the primary epithelioma of the lacrimal sac. It is possible that if every extirpated sac were examined microscopically, a few more cases of primary epithelioma of the sac would be reported. I have never seen such a case, but have had several cases of epithelioma involving the sac due to extension from surrounding structures. I have a patient under my care now with a very much enlarged

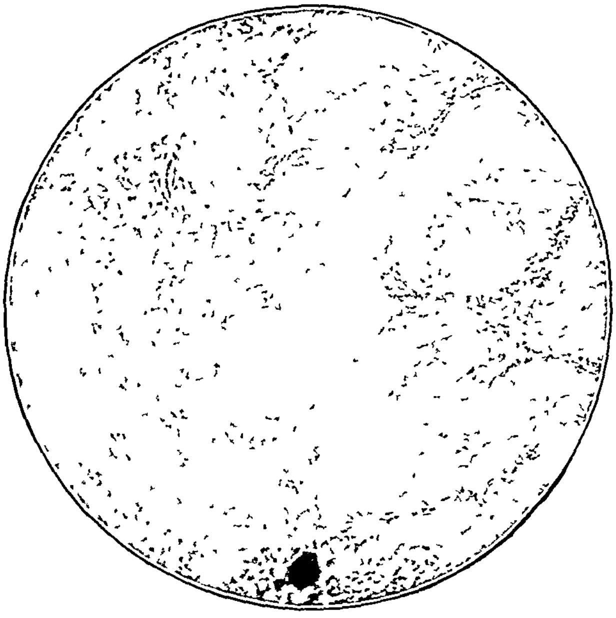

Fig 3.—Irregular masses of cells composing the body of the tumor.

lacrimal sac following an epithelioma of the antrum. Most cases, however, are due to extensions from the skin of the nose or lids. Those epitheliomas of the skin of the nose which have been caused by the irritating effects of eye glasses may, if neglected, readily affect the underlying lacrimal sac. Proper radium treatment will ordinarily take care of epithelioma of the sac which has resulted from an epithelioma of the skin above and surrounding it; but as Dr. Fenton has observed, the radium treatment must be applied by a perfectly competent specialist in this line, and the earlier the better. During the last ten or twelve years I have not resorted to surgical measures for any of the many cases of epithelioma of the skin of the eyelids and nose that I have seen, for the radium treatment in the hands of an expert has been sufficient.

Dr. L. Webster Fox, Philadelphia: Dr. Fenton's opening sentence, "True neoplasms of the lacrimal sac are somewhat unusual," stresses a very important phase of this condition with which observation I heartily concur; namely, its infrequent occurrence. Many epitheliomas involve the lacrimal apparatus by continuity of structure, but primarily malignant disease of this structure is indeed unusual. The differential diagnosis of presumably benign thickening of the sac wall from incipient malignant disease calls for fine exercise of judgment. In the case here reported, the structures were invaded by a slowly growing epithelioma of the nasal integument stimulated in this course by roentgen-ray irradiation, a point of utmost importance to be considered in determining which kind of treatment the more simple cases of skin cancer in this region require. The breaking down of the skin flap which had sustained a measure of destruction by the roentgen ray brings out another point of extreme importance, and this possibility seems not to have been sufficiently emphasized by those handling this type of case. My own experience has embraced every combination of surgery and these several forms of radiotherapy with a fair measure of reasonable success in all; but perhaps the better ultimate results have been obtained by surgery first and the application of radium or the roentgen ray, or both, in the very competent hands of Dr. Pfahler of Philadelphia. To be sure, the very small flat superficial epitheliomas of the skin respond very well to fulguration or radium alone, but many of these are distinctly irritated by even small doses of the roentgen ray, especially when frequently repeated. Cases so treated, as Dr. Fenton has emphasized, do not make the most ideal cases for plastic surgery. Close cooperation is necessary between the surgeon and the roentgenologist, but more especially is this imperative in the case of ophthalmology, as the work is not completed with the destruction of the disease—the cosmetic features of the involved area must be considered together with the maintenance of the normal function of the eye and its appendages.

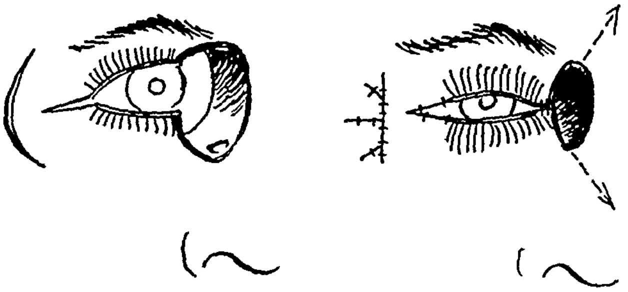

Fig 4.—Plastic operation for moving lids toward nose, reducing defect.

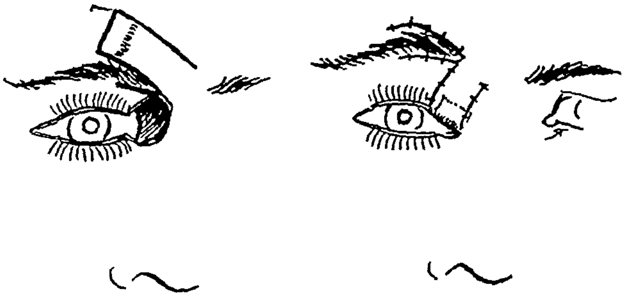

Fig. 5.—Plastic repair of upper lid defect with forehead flap.

Dr. William Campbell Posey, Philadelphia: In addition to the case of primary growth to which Dr. Greenwood referred, I reported another case some years ago. This case was one of chronic inflammatory tumor, with cyst and giant cell formation in the floor of the orbit, and connected with the lacrimal sac, arising after false passages of lacrimal probes. The tumor had arisen in consequence of the forceful passage of probes into the lacrimal duct, this operation having been performed about a year previously to relieve a persistent watering of the affected eye. Following the passage of the probes there had been marked swelling of the lids, and the lids and skin adjacent to them had been discolored for weeks by the blood that had invaded the tissues under the skin. As soon as the pain consequent on the trauma of the operation had subsided, the patient noticed that much of the swelling could be made to disappear by firm pressure, and this was attended by a peculiar crackling sensation. Although the discoloration disappeared after a time, the swelling and crackling sensation elicited by pressure remained, and she soon noted that the former began to assume definite shape, taking the form of a more or less rounded kernel at the inner angle of the eye. Blowing the nose did not seem to increase its volume. When seen by me the tumor was of the size and form of a small butternut in the lower and inner part of the orbit, which gave the impression of a bunch of small angleworms to the examining finger. Firm pressure elicited crepitation and caused the swelling to disappear. The mass appeared to have no connection with the adjacent bone below or with the lacrimo-ethmoidal cells internally, which presented nothing unusual in their external appearance. The mass was exposed by operation and found to be closely connected with the tissues in the region of the sac and those directly below the coujunctival fornix. Dr. George B Wood, who studied the growth, was of the opinion that "the specimen was not a true tumor, but the reaction of tissue to some form of foreign body irritation." From the history of the case, the deduction is reasonable that, at the time that the nasolacrimal duct was probed, the walls of the lacrimal sac or part of the duct were torn and in some way air was forced into the tissues of the lower lid. Subsequent inflations of this tissue due to blowing the nose, etc., kept this opening patulous, and either the pressure of the air in the tissues or the forcing in of lacrimal secretion and minute foreign bodies produced a reaction in the tissues, with the formation of giant cells.

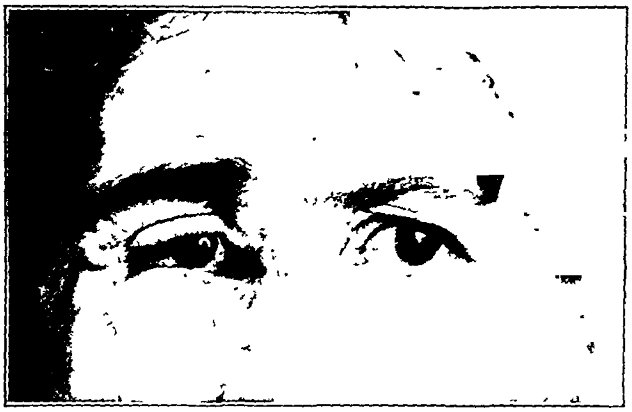

Fig 6.—Results of plastic operation, three months after second operation.

Dr. Ralph A. Fenton, Portland, Ore.: My particular object in presenting this subject is the danger of improper irradiation. We have had our attention called to this subject by surgeons who are finding metastases of carcinoma in various parts of the nervous system, notably the brain, after irradiation has been carried out to a considerable extent in the uterus and other parts of the body. As regards the prognosis of this particular case, it will be noted that the recurrence in the flap is now stationary following massive doses of radium used at one month intervals. However, it is to be anticipated that there will be an invasion. Mosher has pointed out that there will probably be a little invasion of the anterior ethmoid cells, and probably of the antrum.

STUDIES ON GASTRIC ULCER

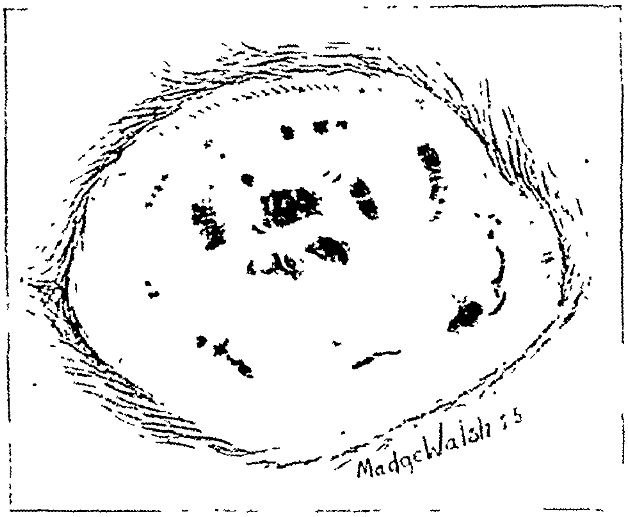
III. THE EXPERIMENTAL PRODUCTION OF GASTRIC ULCER BY LOCAL ALLERGY: PRELIMINARY REPORT

A. C. IVY, Ph.D., M.D.
AND
P. F. SHAPIRO, B.S.
CHICAGO

It occurred to us that acute or chronic ulcers of the stomach might be produced on the basis of the "Arthus phenomenon," or "local anaphylaxis," studied recently in detail by Opie.[1]

METHODS

Rabbits were injected with a protein until a skin ulcer was obtained. The specific protein was then injected aseptically into the gastric mucosa.



Appearance at site of injection, five days after, in Dog 4, which was sensitized to egg albumin, and given an injection of a provocative dose into the stomach pouch after twenty-eight days. The ulcer was 1.8 by 1.4 cm.

Dogs with a pyloric pouch[2] were sensitized to a protein. The provocative dose was injected into the mucosa of the pouch, and into the adjacent skin.

The precipitin titer of the blood was followed in both series of experiments.

RESULTS

The gastric mucosa of the rabbits killed at varying intervals presented the following sequence of pathologic changes at the site of injection: (1) local passive hyperemia and edema in from one to two days after injection of the specific protein into the gastric mucosa; (2) induration and necrosis in from two to five days after; (3) ulceration in from three to six days, and (4) healing with papillomatous overgrowth after twelve days. In one rabbit, an ulcer was still present thirty-three days after. Positive results were obtained with egg albumin, beef protein, oat protein, edestin and horse serum.

In dogs, since the reaction in the mucosa can be observed ad libitum, the pathologic changes can be more accurately described. Within two minutes after injection of the provocative dose, the pouch contracts violently and everts; the mucosa becomes cyanotic and markedly edematous. The next day, at the site of injection, there is a large, bluish black, dried area definitely limited by a thin line of active hyperemia. On the third day, the central portion of the area turns grayish yellow. By the sixth day, the necrotic mucosa has sloughed out, leaving a punched out ulcer with a granulating base. The edges of the ulcer gradually turn in, and healing is complete in from twenty-one to thirty days. Positive results were obtained with egg albumin, beef protein, oat protein, edestin and squash seed globulin.

A second injection of the protein within three days gave no reaction; within from three to seven days it yielded a second ulcer, and after from seven to ten days only a general reaction. The skin reaction was positive, but quite mild, being limited to a slight transient edema.

CONCLUSION

Acute ulcers of the stomach have been produced in dogs and rabbits on the basis of local anaphylaxis to foreign proteins.

SEMINAL VESICLES FROM SYPHILITIC PATIENTS

HISTOLOGIC STUDY *

ELI R. SALEEBY, M.D.
PHILADELPHIA

Warthin,[1] in his classic paper on the new pathology of syphilis, has shown that the testes have a marked susceptibility to infection with *Spirochaeta pallida.* A histologic study of the seminal vesicles from syphilitic patients seemed to be of extreme interest, since these organs are part of the genital system, and especially in relation to the transmission of the disease. A careful survey of the literature, however, has failed to reveal either clinical reports or histologic examination of these organs. At the suggestion of Drs. Kolmer and Schamberg, the present study was undertaken.

MATERIAL AND METHOD OF STUDY

This paper is based on the study of the seminal vesicles from twenty-eight definitely syphilitic cases secured during necropsies performed at the Philadelphia General Hospital. Twenty-one cases presented positive Wassermann reactions during life. In three cases there were no Wassermann reports, but the patients gave a history of chancre, and the tissues, grossly and histologically, presented pathologic syphilitic changes. The remaining four cases gave negative Wassermann reactions, but clinically and pathologically they were considered syphilitic. A few of the cases were neurosyphilitic, and one was a case of congenital syphilis occurring in a 3 months' old negro baby with a positive blood Wassermann reaction.

[1] Warthin, A. S.: The New Pathology of Syphilis, Am. J. Syph. **2**: 425 (July) 1918.

The seminal vesicles were examined and the formaldehyd fixed paraffin sections were stained with hematoxylin and eosin. In our hands the Levaditi silver impregnation stain, for the demonstration of *Spirochaeta pallida,* proved the most satisfactory, and we used it as a routine in this study. To insure a good technic I included a piece of control tissue with each one of which was a portion of liver from a congenitally syphilitic fetus in which the spirochetes previously were demontrated by the Levaditi silver impregnation method. Paraffin sections of formaldehyd fixed seminal vesicles of ten nonsyphilitic subjects, of variable ages, were stained with hematoxylin and eosin and studied to compare with the syphilitic material. This was necessary because the textbooks give a sketchy and variable description of the normal histology. In the study of the sections, particular attention was directed to the condition of the blood vessels, since they are known to have a special susceptibility for the organism and show the greatest degree of change in the disease. The testes and the inguinal glands were also removed and studied in all cases; the findings will be reported at a later date.

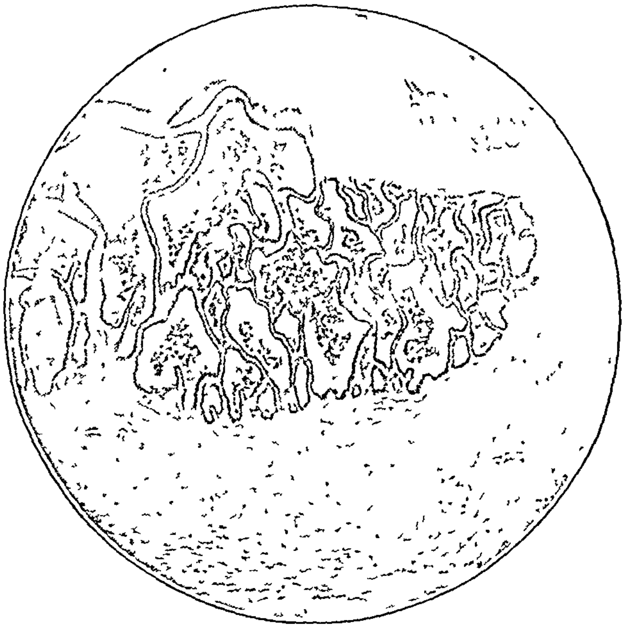

Fig. 1.—Section of the seminal vesicles showing the general structure

RESULTS

Grossly, the size of the seminal vesicles varied with the age of the subject and with the fluid content. In no instance was I able to determine any difference between the syphilitic and the nonsyphilitic organs either in the thickness of the walls or in the contents, although as a rule the quantity of the fluid was less in the syphilitic cases.

The histologic picture of the sections from the syphilitic subjects varied. The epithelial lining varied from one to three layers of cylindric, cuboidal or simple stratified cells; in some cases there was a total atrophy of this lining. The amount of the fluid did not have any appreciable effect on the shape of the epithelial cells. External to the fibrous and elastic submucosa there was a smooth muscular coat of two and three layers—inner and outer longitudinal and middle circular. The three layers appeared in the main part of the organ and the two layers in the diverticular parts. In some diverticula, only one layer was demonstrable. The contents of the cavities consisted of débris from degenerated epithelial cells, fatlike globules and pinkish stained homogeneous material, which probably was the secretion from these organs. In eight of the sections spermatozoa were noted, and in five others some dark stained granules were seen and considered to be the heads of the degenerated spermatozoa.

None of the cases showed syphilitic changes in the structure of the organ proper. Two cases presented definite involvement of the blood vessels, but these vessels were external to the outer muscular layer. The adventitia and the media exhibited marked proliferation, with perivascular infiltration of plasma cells and many lymphocytes. Both patients had syphilitic aortitis; one died from ruptured thoracic aneurysm and the other from cardiorenal disease. Neither the epithelial structure nor the musculature of the seminal vesicles showed any definite syphilitic changes.

The vessels in many of the other sections showed some degree of sclerosis, with proliferative changes and perivascular lymphocytic infiltration with no plasma cells. However, similar changes were noted in sections of the vesicles from the nonsyphilitic subjects. In none of the Levaditi stained sections was I able to demonstrate the presence of *Spirochaeta pallida,* though every control was positive.

COMMENT

In 1920, Thompson,[2] in his papers on the history of syphilis in the genital organs, stated that syphilis of the seminal vesicles has never been shown, and most authors either ignore the subject or remark that it is rare. A careful survey of the literature failed to show any reported cases. My findings certainly confirm the general belief about the rarity of syphilis of this organ. In the two cases in which I was able to demonstrate vascular (syphilitic?) changes histopathologically, the lesions were confined to the vessels outside the outer muscular layer, and in neither of these could *Spirochaeta pallida* be demonstrated. These intricate organs

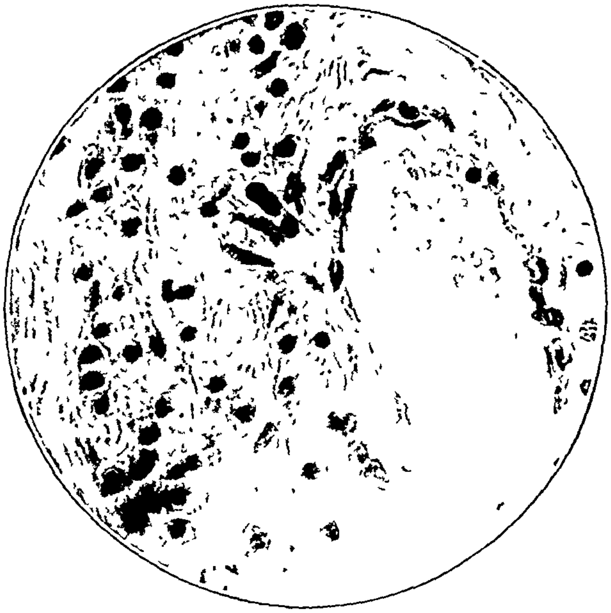

Fig. 2.—Section from a syphilitic case showing perivascular round cell infiltration with many plasma cells and lymphocytes

vary in different specimens and in different parts of the same organ. This probably accounts for the conflicting statements in the various textbooks.

---

[2] Thompson, Lloyd: Syphilis of the Genital Organs of the Male and the Urinary Organs, Am. J. Syph. 4: 706 (Oct.) 1920.

The contents of the seminal vesicles were examined by Brack[3] in 500 cadavers (1920-1922), and no spermatozoa were found in 47 per cent. of the total.

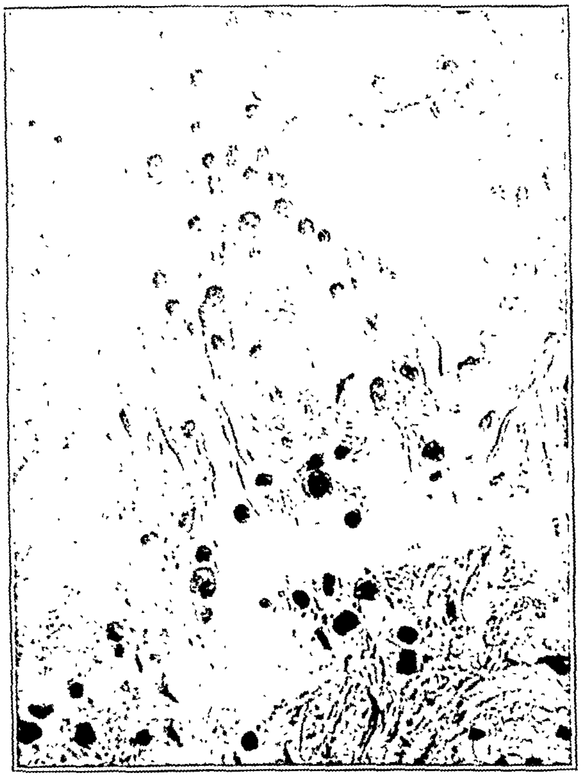

Fig. 3.—Section from another syphilitic case showing changes similar to those in Figure 2.

The absence of the spermatozoa and their disintegrated parts in fifteen of the syphilitic sections is a noteworthy incidence. Without further study it is difficult to state whether syphilis influenced their absence. But their absence from these and four of the nonsyphilitic sections strengthens the belief that their primary function is secretory and their function as a reservoir is secondary. The vas deferens is apparently the organ that acts as a reservoir for the testicular secretion.

It is beyond the scope of this paper to discuss the function of these organs. Moulin,[4] recently, reviewed this subject thoroughly. Most of the authors agree that the seminal vesicles have an important secretion. Its importance is not only in supplying a medium favorable for the motility of the spermatozoa and diluting the testicular secretion but also in completing the volume of fluid for ejaculation. Whether they are indispensable for copulation and fecundation is still open for conjuncture and needs further study.

SUMMARY AND CONCLUSION

The seminal vesicles from twenty-eight syphilitic human subjects were studied grossly and histologically. In none of the sections were syphilitic lesions noted, except possibly in two, in which the vessels in the serosa showed perivascular round cell infiltration of many plasma cells and lymphocytes. The presence of *Spirochaeta pallida* could not have been demonstrated in any of the sections stained by the Levaditi silver impregnation method. The findings in this investigation indicate that syphilis of the seminal vesicles is very rare.

1426 Spruce Street.

ABSTRACT OF DISCUSSION

DR. JOHN A. KOLMER, Philadelphia: Apparently no organ of the human body is completely invulnerable to infection with *Spirochaeta pallida*, and this study is of particular value in connection with the mechanism of conceptional syphilis. It is well known, for example, that the testes may be infected with the spirochete. This is not based on clinical detection, because the familiar clinical lesion of testicular syphilis, the billiard ball lesion, is distinctly uncommon. But we now know that histologic examination of the testes of syphilitic patients shows a high incidence of infection. The prostate gland would appear probably to be next in frequency in percentage of infection, although there are not more than thirty odd cases of syphilis of the prostate gland on record. But, curiously enough, the literature has been very silent on the matter of infection of the seminal vesicles. I know of no reported case of syphilis of this organ, and the findings of Dr. Saleeby in the one or two cases are only suggestive at best. The mild degree of perivascular round cell infiltration is suggestive, but by no means conclusive. It would remain to show whether or not the gonococcus could produce histologic changes of this degree in this organ. It is particularly significant that, despite a great deal of labor in going over the slides, spirochetes were not found. Thanks to the work of Dr. Warthin, we are prepared to find that the spirochete might be present in the tissue without a great deal or even probably without any demonstrable degree of round cell infiltration, but the sections of these organs were entirely negative for the spirochete. I think the finding is of considerable interest, and very probably the testes are to be looked on as the most important organ of the genital system in relation to the conceptional transmission of syphilis.

Clinical Notes, Suggestions, and New Instruments

ACTION OF DIATHERMY IN CALCIFIED SUBDELTOID BURSITIS

Joseph F. Harris, M.D., New York
Associate Physical Therapist, Mount Sinai Hospital

E. M., a man, aged 52, a musician, was referred to me, Jan. 21, 1925, complaining of a painful left shoulder with inability to raise his left arm from his side. He stated that this condition had been present seven years with intermittent attacks of inability to raise the arm. The roentgenograms verified the diagnosis of calcified subdeltoid bursitis (January 19). He received his first treatment, January 21, and at the end of two weeks' treatment he was able to resume his occupation, that of a musician, playing a bass viol in a symphony orchestra. Some pain, however, persisted, and it was necessary in all to give him thirty-two treatments, at the end of which time all the symptoms, namely, pain and restricted motion, had disappeared. Roentgenograms were again taken, April 6, and showed an absorption of the greater part of the deposit. These pictures, forming the case record, show the diagnosis and the result of the treatment by diathermy.

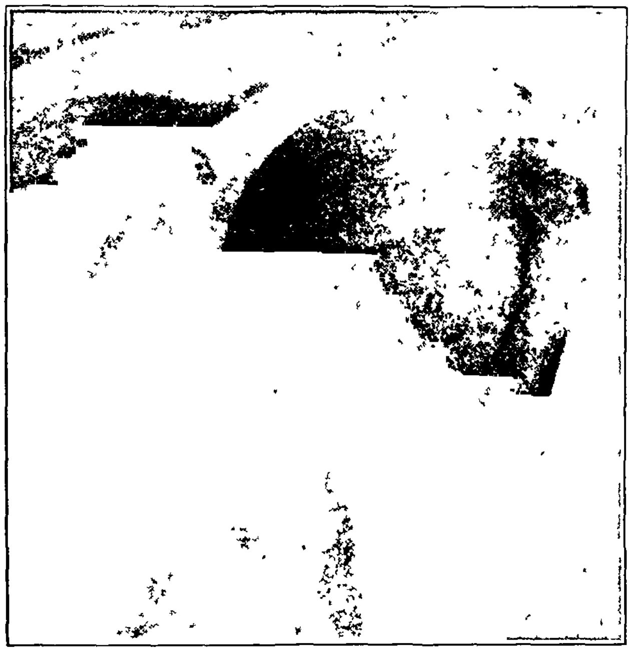

Fig. 1.—Appearance and size of deposit before treatment (January 19).

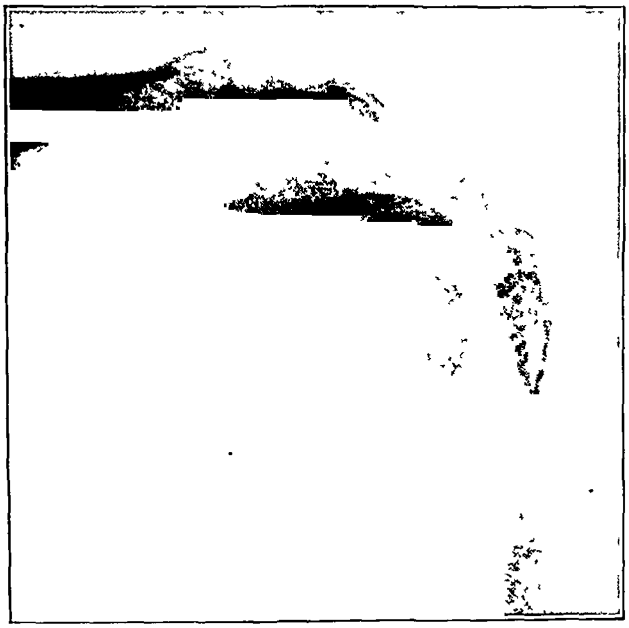

Fig 2.—Nearly complete absorption after course of treatment by diathermy (April 6).

The accompanying illustrations show conclusively that diathermy is a curative measure and not a palliative one. A long series of cases treated over a period of years has shown a complete restoration of function and an absence of pain. It is therefore fair to assume that in each case the greater part of the deposit has been absorbed by this form of treatment. If not completely absorbed, it has been reduced to such a size that it does not interfere with the function of the shoulder. Up to this time I have not seen a recurrence. I do not hesitate to say that this is the treatment *par excellence* for this condition.

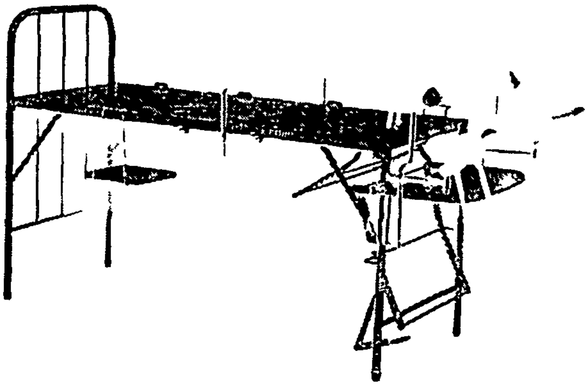
A NEW DELIVERY BED

George Gellhorn, M.D., St. Louis

The delivery beds in common use in this country have one or more of the following distinct shortcomings:

1. The legs of the patient in labor must be held by attendants. This is a drain on the nursing force, which is none too ample in any hospital, and seriously cripples the nursing service at night. Moreover, nurses who act as human leg holders are unable to watch the process of labor and thus miss at least one important part of their training. If the second and third stages are at all prolonged, the actual physical effort is not inconsiderable.



New delivery bed.

2. Mechanical leg holders, on the other hand, are by no means satisfactory. Of the various types in use, the straight leg holder, in which the foot of the patient is secured in a vertical elevation, imposes a noticeable strain on the sacro-iliac ligaments, leaves the patient with backache for some days after delivery, and may be the cause of protracted sacro-iliac disease. Another type of leg holder provides support only for the knees and leaves the lower limbs and feet hanging free. This almost regularly leads to unpleasant paresthesias; "the feet fall asleep."

In either type of leg holder the legs are elevated and thereby the perineum is put on a stretch which, when superimposed on the pressure exerted by the advancing head, may be conducive to deeper lacerations.

3 Whether the patient's legs are steadied by nurses or in leg holders, the pelvic outlet is tilted more or less upward,

which, theoretically at least, requires more force from behind for the expulsion of the child.

4. More important, to my mind, is the fact that, with her feet in the air, the patient is unable to utilize the abdominal muscles to best advantage during the last part of the second stage and before she is fully anesthetized.

5. Whether held by nurses or by mechanical devices, the patient may—and quite regularly does—change her position at the edge of the obstetric table or bed. Even a beginner in obstetrics gathers this experience soon. Frequently the patient becomes unmanageable in the interval between the superficial obstetric and deep surgical anesthesia; the nurses are pushed hither and yon, and many a twisted or bent leg holder, all over the country, bears mute testimony to the struggles of the patient. Just when forceps are to be applied or a version is to be made or stitches inserted in a lacerated perineum, the patient may make an unconscious defensive effort and push herself up on the table and away from the obstetrician. This frequently means not only a loss of time but—what is more important—a disarrangement of the carefully applied sterile draperies and a break in asepsis.

I have endeavored to overcome these various difficulties by a novel but simple attachment to the lower end of an ordinary delivery bed. The latter is of comfortable height and width and of sturdy construction. The comfortable and roomy footrests of metal, shaped like the wooden shoes of the Dutch peasant, are on a height with the table, that is, on the same level as the back of the patient, and can be adjusted to any distance from the table. Connected with the foot rests are well rounded knee supports, which also are easily adjusted to the individual patient. Between the foot rests, but a few inches below them, is an extension table or shelf which may be turned down by pressing on a pedal. A simple arrangement permits one to raise the lower end of the table for the few occasions when an elevation of the pelvis is desired for obstetric manipulations, such as reposition of the prolapsed cord. The table itself is covered with a mattress, one inch in thickness, which is composed of spongy rubber; it is both firm and resilient and can readily be scrubbed and kept clean (not shown in the illustration).

When the patient reaches the second stage of labor, she is moved toward the lower end of the bed until the buttocks are even with, or one-half inch beyond, the edge. The feet are placed, at a comfortable distance, in the footrests and secured there by a washable strap round the ankles. The knee supports are pushed upward until the knees rest securely in them; another strap is then fastened across the knees, so that these cannot be lifted out of the supports. The legs may be kept parallel to each other or, if greater exposure of the perineum is desired, divergent and held in their position by the turning of a screw. Shoulder braces, which are padded with the same spongy rubber that covers the table, are now adjusted; and the patient, while in a perfectly comfortable position which she may keep for hours, is unable to move either forward or backward on the bed. There is enough play both in the foot rests and in the knee supports to exclude even the slightest sensation of being incarcerated. In this position she can make the best possible use of her auxiliary musculature, and she is aided in this by handles at the side of the table on which she may pull.

When actual delivery draws near, the vulva is disinfected in the usual manner (we use soap and water and follow this with a watery, 1.5 per cent. solution of picric acid), the adjustable shelf between the legs is covered with a pillow, and three large, sterile sheets are placed, one over this shelf and pillow and one over each leg and covering the abdomen. The shelf serves for the reception of the child and, later, for instruments needed for repairs.

The obstetrician, at all times, has an unobstructed view of the birth passage. I have the impression, though this would be difficult to prove statistically, that the perineum is more relaxed and traumatisms are reduced, other things being equal. Obstetric operations are undoubtedly of greater ease than with the feet elevated. Antiseptic and aseptic preparations, once made, are not disturbed throughout the course of the delivery.

Before the anesthetist starts the narcosis, the hands of the patient are secured in a leather sling, which eliminates any annoying interference on the part of the slightly narcotized patient. Two trays firmly attached beneath the bed on either side contain all the appurtenances for the narcotizer; this arrangement does away with an additional narcotizer's table in the delivery room.

From this description it will be seen that the personnel for delivery is greatly simplified. There is the obstetrician and his assistant or an instrument nurse, and the anesthetist, and merely one circulating nurse. Other available nurses may watch the progress of the delivery; for the patient, once in her final position, requires no further attention.

There may be instances in which the arrangement as outlined is not desired. The operator may, for example, wish for an elevation of the legs and a stretching of the perineum. This is readily accomplished by pushing the foot rests upward and fastening them in this position. Dwarfs or giantesses cannot be accommodated, but no arrangement can possibly be made for such exceptional instances. For all other cases, that is to say, for practically our entire obstetric work, the new bed answers every requirement. We have used it in almost 500 deliveries and have found it uniformly satisfactory. The simplicity of its construction, its stability, and the moderate price are further advantages.[1] The importance of the subject, the comfort of both patient and obstetrician, the safety of our manipulations, the saving of labor and the resulting benefit to hospitals and nurses' training schools have seemed to me to justify a somewhat detailed description.

Metropolitan Building.

A CASE OF MARKED SPLENOMEGALY AND LYMPHOCYTOSIS ASSOCIATED WITH SYPHILIS

Arch Elkin, M.D., and Harold M. Bowcock, M.D., Atlanta, Ga.

A moderate degree of splenomegaly is a frequent finding during the course of syphilitic infection. Marked splenomegaly is sometimes encountered, and Giffin[2] has reported three such cases which were treated surgically because of absence of improvement under antisyphilitic treatment. Other cases[3] have been reported in which splenomegaly was associated with syphilis accompanied by a clinical picture resembling Banti's disease We have been unable to find in the literature the report of a case similar to the one reported here, in which the clinical picture at first suggested an atypical leukemia, and later Banti's disease, and in which antisyphilitic treatment was attended by marked improvement.

REPORT OF CASE

History.—A widowed white man, aged 47, seen Aug. 25, 1924, complained of pains in the left side of the abdomen and chest, and weakness. His father had died at the age of 59 from alcoholism, and his mother had died at the age of 56 from chronic interstitial nephritis; the family history was otherwise unimportant. During 1902, the patient had had a sore on the penis which had been diagnosed as a chancre. The treatment had consisted of tablets and a tonic over a period of two years. During 1908, he had had an operation for mastoiditis. During 1914, he had felt bad and had been given an intravenous injection of arsphenamin and had taken a liquid medicine for six months. During 1918, he had had an attack of influenza with complete recovery. During 1921, the first blood Wassermann test had been made and reported negative. The remainder of the past history was unimportant. For two weeks, the patient had suffered from pain which started suddenly beneath the left costal margin, radiating across the abdomen to a corresponding position on the right side. The pain had not been very severe and was of a drawing character. He had consulted a physician who had treated him for pleurisy without relief. For one week, he had suffered from weakness and anorexia.

Quoyrat, L.: Syndrome de Banti et syphilis, ibid. **38**: 296, 1914.

Physical Examination.—The patient was well developed and fairly well nourished. The skin and mucous membranes were pale. The left tonsil was large and cryptic. Many superficial glands were palpable, and some seemed to be slightly enlarged. There was some bulging of the entire left abdomen, and there was a firm tumor mass extending from the left costal border downward to the region of the umbilicus and to the right, about 2.5 cm. beyond the umbilicus; no notch was felt. The urine gave slight reduction of Benedict's solution. There was a moderate secondary anemia; the white blood cell count was 49,250, of which 90 per cent. were small mononuclears, 8 per cent. polymorphonuclear neutrophils and 2 per cent. large mononuclears. The blood Wassermann reaction was reported to be negative. The remainder of the examination revealed normal findings.

Course.—The diagnosis of an atypical leukemia was made, and the patient received five roentgen-ray treatments during five days. The temperature varied between subnormal and 103.4 F., and the pulse rate between 86 and 130 a minute during the time of treatment. Several weeks later, the spleen was no longer palpable, and the patient resumed his occupation of a traveling salesman. While on the road, he received sodium cacodylate in 5 grains (0.3 gm.) hypodermic doses twice weekly. He continued to feel well until about Jan. 1, 1925, when he again started to suffer from weakness and pains in the left upper quadrant. January 10, the spleen was found to be quite large, but the white blood cell count was only 5,250. The differential count was: polymorphonuclear neutrophils, 50 per cent.; polymorphonuclear eosinophils, 1 per cent.; small mononuclears, 37 per cent.; large mononuclears, 10 per cent., and neutrophil myelocytes, 2 per cent. He was readmitted to the hospital, January 20. On examination there was a marked icteric color of the skin. There was a firm, smooth, tumor mass extending from the left costal margin downward 2 cm. below the level of the umbilicus, and 2 cm. to the right of the umbilicus; no notch could be felt. The liver edge was palpable 5 cm. below the right costal margin; the surface was smooth, and the edge was firm. The urine contained a trace of albumin and gave a positive reaction for bile. The red blood cell count was 2,720,000, the hemoglobin was 44 per cent. (Dare), and the white blood cell count was 4,500. The differential blood count showed polymorphonuclear neutrophils, 47 per cent.; polymorphonuclear basophils, 2 per cent.; small mononuclears, 49 per cent.; large mononuclears, 1 per cent., and transitionals, 1 per cent. The icterus index of the blood serum was 60, a 1:10,000 solution of potassium dichromate being used as a standard.

The patient's condition changed rapidly to a drowsy semicomatose state with the temperature curve varying rapidly between 96 and 104.8 F., and the pulse rate varying between 100 and 140 a minute. There was marked anorexia, nausea and vomiting. Because of the patient's rather critical condition and the blood picture, a transfusion of the blood was considered advisable. There was some delay in finding a satisfactory donor, although the recipient's blood belonged to Type IV, and while continuing in the search, 0.45 gm. of neo-arsphenamin was given intravenously, January 25. Three days later, a transfusion of 300 c.c. of whole blood was performed by the Unger method without a reaction. Following the neo-arsphenamin, the temperature dropped quickly and did not rise above 100 F. After the transfusion, the improvement was so rapid that it seemed unlikely that the results could be due to such a small amount of blood. Consequently, February 2, he received a second injection of 0.45 gm. of neo-arsphenamin, and a Wassermann reaction was done on the blood; the report was complete fixation.

Following this injection, the improvement in the patient's condition was remarkable. In a few days, the spleen and liver had decreased in size, the jaundice had lessened perceptibly, the temperature and pulse rate had returned to normal, and the patient felt better in every way. February 5 and 8, he received 0.6 gm. doses of neo-arsphenamin, and each was followed by a reaction with headache and elevation of temperature; with the second reaction, the temperature rose to 103.5 F., and then returned to normal. February 11, he received 0.3 gm. of neo-arsphenamin and, February 14, 0.45 gm. without a reaction. February 15, the patient's general condition was so much improved that he was permitted to leave the hospital. On discharge, the icterus had entirely disappeared, the liver was no longer palpable, and the splenic edge was felt only 2 cm. below the costal margin. The red blood cell count was 4,600,000; hemoglobin, 55 per cent., and white blood count, 3,000. The differential count showed: polymorphonuclear neutrophils, 55 per cent.; small mononuclears, 30 per cent.; large mononuclears, 13 per cent., and transitionals, 2 per cent. After leaving the hospital, the patient developed an arsenic dermatitis with burning, redness and desquamation of the skin. During the period of the dermatitis and for about three weeks subsequently, three differential counts showed from 8 to 12 per cent. polymorphonuclear eosinophils, while the white blood count varied between 5,600 and 7,000. Because of his intolerance to arsenic, the patient was placed on a regimen of potassium bismuth tartrate, 0.2 gm. intramuscularly, once a week. March 28, the spleen was no longer palpable even with deep inspiration. April 8 and ten days later, 0.3 gm. doses of neo-arsphenamin were given, resulting in the reappearance of a slight arsenic dermatitis. May 1, the red blood cell count was 4,050,000; hemoglobin, 96 per cent. (Dare), and white blood cell count, 6,500. The differential count was normal except for the reappearance of an eosinophilia of 6 per cent. The blood Wassermann reaction, as on several previous occasions, was strongly positive. Aside from the remains of the dermatitis, the patient presented no abnormality and considered himself in excellent condition.

SUMMARY

In this unusual case, there was marked splenomegaly and a high lymphocyte count improving with roentgen-ray therapy, and later, reappearance of splenomegaly, secondary anemia, leukopenia, enlarged liver and jaundice, and the discovery of a positive Wassermann reaction with rapid and marked improvement with antisyphilitic treatment.

436 Peachtree Street.

A CASE OF CYSTICERCUS OF THE SKIN

Zach B. Coblentz, M.D., Santa Maria, Calif.

A man, aged 25, a Mexican, while working in the lettuce fields, noticed, July 10, 1925, an inability to talk, as if his tongue was paralyzed. He then became unconscious for a period of forty-five minutes. During this attack there was marked dyspnea. There was no frothing at the mouth; the eyes were closed; he did not bite his tongue, and there was no muscular twitching. All of these details were reported to me by the foreman, on my arrival.

I found the patient sitting up; there was some dyspnea. A hasty examination revealed nothing abnormal. The next day the patient came into my office, and a thorough examination disclosed the patient to be normal, except for several freely movable nodules about 1 cm. in diameter lying subcutaneously and apparently not attached to the underlying tissues. The urine was normal, and a blood smear showed the normal ratio. There were nine of these nodules distributed over the chest, three on the arms and one on the neck. None at all appeared from the waist line down. Under procain, one of the nodules was removed. On removal, an incision into it showed a clear fluid. The capsule was sent to Dr. William Ophuls, who reported that it was an ovoid cyst about 1 cm. in diameter, containing the head of a tapeworm and surrounded by a dense fibrous capsule; cysticercus, subcutaneous tissue of chest wall.

The patient had always enjoyed good health. He had never had any tenia, as far as I am able to ascertain. Requests for specimens of feces have been ignored.

The patient is not of the nervous type, never had any such attacks before, and has been working in the fields for years. It is certainly suggestive of a cysticercus in perhaps the fourth ventricle.

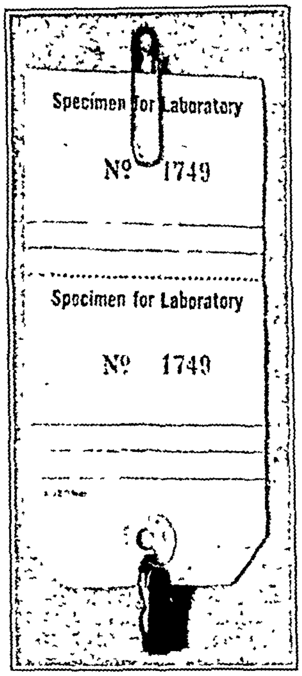
I am reporting this case because, in reading the literature, I have noticed the infrequency with which cysticercus of the skin is encountered.

THE IDENTIFICATION OF SPECIMENS FROM THE OPERATING ROOM *

WILLARD S. HASTINGS, M.D., ROCHESTER, N. Y.

A prominent surgeon who is unusually familiar with laboratory problems, when visiting this hospital recently, showed an unexpected interest in the system employed for the identification of specimens sent from the operating room to the laboratory, and commented on the usual lack of such a plan elsewhere. On having our attention thus drawn to the matter, we have not been able to recall seeing anything of the sort in use in other places and therefore venture a brief description, though it is such an obvious application of methods familiar in other fields that no report of it had previously been contemplated.

The opportunities for serious confusion, loss and delays, with consequent damage to the specimen, that may occur between the operating room and the laboratory are too evident to need enumeration. In spite of rather rigid rules intended to keep a specimen and its history sheet together, there were several instances in the past which might have been more unfortunate than they were. To avoid these a tag, easily separable into two parts bearing duplicate numbers, has been provided. A spring clasp, or "card-holder" (Dennison's No. 46), is hooked into the eyelet as illustrated, and an ordinary paper clip provided for the opposite end. The card-holder was selected after some search for a clasp which was to be found in the stores and which could be attached to the tag easily, and could then be fastened with equal ease on the edge of an enameled specimen dish, on the lip of a bottle or to a gauze package, or bitten into the edge of a cork. It has proved very satisfactory, though a similar clasp bearing something in the nature of a paper clip in place of the hook on this one would be an improvement.



Tag with card-holder and clip as used for the identification of laboratory specimens.

A few tags thus equipped are always available in the operating room. Whenever a specimen is ready, a tag is torn in two and the clasp end attached to the specimen dish, which is sent to the laboratory at once, or as soon as any one can be spared for the purpose. The opposite end of the tag is clipped to the operation sheet. When the latter is made out after the operation, a specimen sheet is also filled in with data necessary for the proper study of the specimen, and the tag transferred to this sheet and sent to the laboratory. Lines are provided in both halves of the tag for any special instructions. For instance, if a specimen is to have a culture taken, it should be so marked to avoid its being placed at once in fixing solution. The numbers on the tags are used only for the temporary purpose of identification, and no attempt is made to keep them in accurate sequence, though it has been found convenient to have them so in a general way.

---

* From the Department of Laboratories, Highland Hospital.

Testicular and Ovarian Medication Ineffective.—Extracts of ovary and testis produce no noticeable effects in health or disease when given by mouth. When administered subcutaneously the commercial preparations appear to be for the most part inactive, and, at the best, only produce a slight irritant effect, just as do extracts from all kinds of organs and tissues.—Vincent, Swale: *Proc. Royal Soc. Med* **18**:32 (June) 1925.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

PROTEIN S. M. A. (ACIDULATED).—A modified milk preparation having a relatively high protein content and a relatively low carbohydrate content. Each 100 Gm. contains approximately protein (of milk), 35 Gm.; S. M. A. fat (consisting approximately of tallow oil 0 to 10 per cent.; coconut oil, 15 per cent.; cacao butter, 20 per cent.; cod liver oil, from 7.5 to 12.5 per cent.; tallow, from 45 to 55 per cent.), 22 Gm.; carbohydrate (lactose), 28 Gm.; ash, 6 Gm.; moisture, 2 Gm.; desiccated lemon juice, equivalent to 16.7 Cc. of fresh juice. The content of lactic acid is regulated so that when the product is diluted according to directions the liquid will have a p_H 4.6.

Actions and Uses.—Protein S. M. A. (acidulated) is stated to differ from protein milk in that, when prepared according to directions, it is higher in protein and lower in carbohydrate. Its use in the feeding of infants is proposed as a means of checking diarrhea; in malnutrition and marasmus, and the feeding of prematurely born infants needing a high caloric intake.

Dosage.—For use, one ounce of protein S. M. A. (acidulated) is mixed with 9 fluidounces of warm water; first a smooth paste is made with a little warm water and then the remainder is added with thorough stirring. The mixture is added to the diet in increasing quantities as indicated; carbohydrates may be added.

When diluted according to directions the mixture contains protein, 3.5 per cent.; fat, 2.2 per cent.; carbohydrate, 2.8 per cent.; ash, 0.6 per cent.; it has a p_H of 4.6 and represents 50 calories per hundred cubic centimeters (15 calories per ounce).

Manufactured by the Laboratory Products Co., Cleveland. No U. S. patent. U. S. trademark applied for.

TETRABROMOPHTHALEIN SODIUM (Formerly called Tetrabromphenolphthalein Sodium, see New and Nonofficial Remedies, 1925, p. 141).

Bromeikon.—A brand of tetrabromophthalein sodium-N. N. R.

Manufactured by the Mallinckrodt Chemical Works, St. Louis. No U. S. patent or trademark.

Bromeikon, 5 Gm. Ampules.

TYPHOID VACCINE (See New and Nonofficial Remedies, *1925*, p. *360*).

H. K. Mulford Co., Philadelphia.

Typho-Bacterin (See New and Nonofficial Remedies, 1925, p. 363).—Also marketed in packages of thirty 1 Cc. vials (M193-5) (hospital size), being ten sets of three immunizing doses containing, respectively, 1,000, 2,000 and 2,000 million killed typhoid bacilli.

NORMAL HORSE SERUM (See New and Nonofficial Remedies, *1925*, p. *329*).

Eli Lilly & Co., Indianapolis.

Normal Horse Serum.—The serum of the blood of the normal horse obtained in a sterile manner and passed through a Berkefeld filter. Marketed in packages of one syringe containing 10 Cc.; also in packages of one vial containing 20 Cc.

PERTUSSIS BACILLUS VACCINE (See New and Nonofficial Remedies, 1925, p. 353).

Eli Lilly & Co., Indianapolis.

Pertussis Vaccine.—A suspension of killed *Bacillus pertussis* in physiological solution of sodium chloride, preserved with 0.3 per cent. of cresol. Marketed in packages of four 1 Cc. vials containing, respectively, 250 million, 500 million, 1,000 million and 2,000 million killed bacteria per cubic centimeter; in single 5 Cc. vial packages containing 2,000 million killed bacteria per cubic centimeter; in single 20 Cc. vial packages containing 2,000 million killed bacteria per cubic centimeter; and in packages of four 1 Cc. vials, each containing 2,000 million killed bacteria per cubic centimeter.

SATURDAY, OCTOBER 10, 1925

SOME FUNDAMENTAL FEATURES OF THE CIRCULATION

A conspicuous feature of the modern application of the sciences in the service of mankind has been the development of quantitative methods and the extension of their use in many fields. The physician of today deals with relatively exact figures in connection with basal metabolism, the circulating sugar and the nitrogenous catabolites of the blood, the respiratory gases, hydrogen ion concentration of tissue fluids and artificial solutions, the efficiency of the optical and auditory outfits of the organism, and the pressure of the blood—to cite illustrations of measurements unknown to physicians of a generation or two ago. Interest in the qualitative aspects of life has become supplemented by a realization of the advance that a better quantitative knowledge of the functions of the body is likely to promote.

It has recently been remarked that the circulation, respiration, production of heat, and performance of work are all merely parts of the one general process of the body's energetics. With respect to most of these factors, well established data of widespread applicability are now available. Henderson and Haggard[1] of Yale University have pointed out, however, that the circulation has heretofore been so nearly entirely unmeasurable that few well defined terms, and no system, are available in which to present data. By way of contrast, they remind us how in the closely related field of the respiratory exchange and indirect calorimetry the central conception is that of the basal metabolism: the volume of oxygen consumed and the corresponding number of calories produced per square meter of surface in a given time, at rest in the postnutritive state. Thanks to these resourceful physiologists, one of the outstanding unsolved problems of the circulation, that of the volume flow of blood per minute, has been opened to attack with greater prospects of real success than ever before. They have developed a simple and fairly accurate method for measuring the circulation in man and thus of ascertaining the functional efficiency of the circulation in persons under all sorts of conditions. The details of the novel procedure, which includes measurements of the absorption of the slightly soluble vapor of ethyl iodid and estimation of its comparative content in the inspired air and the arterial blood, are too technical to warrant discussion here. The outlook for securing dependable measurements of the circulation on the untrained human subject with a minimum of inconvenience is highly encouraging.

Some of the results already obtained are rather unexpected. They show that in healthy, vigorous persons the circulation performs its respiratory functions with a remarkable high efficiency and thereby supplements the work of respiration most advantageously. According to Henderson and Haggard, to make the adjustment necessary when muscular work is performed and particularly to meet the increased demand for oxygen, the circulation has three reserves: increase of the pulse; increase of the heart stroke volume; and increase of the arteriovenous oxygen difference, or percentage utilization. They assert that for an exertion no greater than the ordinary activities of life, increase in the pulse is the chief compensatory factor. As soon, however, as such moderate activity is exceeded, increase of stroke volume and of oxygen difference is also involved, along with a further increase of the heart rate. The increase of the stroke, they find, seems to reach its limit at a "stroke index" of about 3.5 c.c. per kilogram of body weight, an oxygen consumption of about 2 liters, and a circulation of about 35 liters per minute. Beyond that point the oxygen difference in the blood increases because the circulation does not. The strain on the subject then increases to his limit of power. The demand is satisfied from the third reserve—the oxygen store in the blood; but this involves a decrease of the partial pressure of oxygen in the tissues, and an increasing oxygen deficit. The latter, Henderson and Haggard conclude, has to be made good after the termination of the period of work.

The arteriovenous oxygen difference expresses the relation of the activity of the circulation to the intensity of the calorific and respiratory processes. When the usual volume of blood per minute for each unit of metabolism transports the oxygen required for the latter from the lungs to the tissues, the arterial blood must contain about 4 per cent. by volume more oxygen than the venous. In other words, the circulation is ordinarily so large in relation to the oxygen consumption of the body that the venous blood returning to the right side of the heart contains on the average only 4 per cent. by volume less oxygen than the arterial blood. Henderson and Haggard estimate that the blood stream pumped by the heart is about twice as large as was formerly supposed. During bodily rest its volume in liters per minute is about equal to the volume of air breathed in that time. During exercise, respiration may increase eight or ten fold, and the circulation four or five fold. It is estimated that the maximum power of the heart is about equal to the amount of work involved in lifting the weight of the body one meter per minute.

---

[1] Henderson, Yandell; and Haggard, H. W.: The Circulation and Its Measurement, Am. J. Physiol. 73: 193 (June) 1925.

Certain incidental observations of the circulation are of clinical interest. Hot baths quicken the circulation without greatly increasing the oxygen consumption. In this way they reduce the "oxygen difference" and thus raise the pressure of oxygen in the tissues. During vigorous exercise, the increase in the circulation may not keep pace with the oxygen consumption, so that the oxygen difference increases because the circulation does not. In patients with heart disease, the inefficiency of the circulation may show itself in the increase of the arteriovenous oxygen difference above the normal value. Hence, Henderson and Haggard point out, the capacity of the circulation to keep the oxygen difference down, and thus to keep the oxygen pressure in the tissues up, appears to be the limiting factor in the maximum power that can be sustained by athletes at one end of the scale, and by patients with heart disease at the other.

THE AGING OF NATURAL MINERAL WATERS

When science and traditional experience clash, it is often well to preserve an open mind, for our knowledge is finite, and, while carefully garnered facts have a permanence of value that cannot easily be thrust aside, the new acquisitions sometimes compel a revision of the point of view or permit a different approach to a debated subject. The coming years are likely to afford various illustrations of this in such poorly cultivated fields as climatology. There is a long series of traditions and a not inconsiderable group of empirically attested opinions regarding the relations of light, air and water to human well being. Some of them are too deeply rooted to be easily brushed aside even when no plausible explanation is at present forthcoming. Others have yielded to scientific investigation to the extent of disclosing an interpretable justification for the long held beliefs. Sunshine embodies forms of radiant energy that the laboratory has clearly demonstrated to be therapeutically potent. There are less well defined effects of air and water on the metabolism and circulation. Some of them are not more elusive than the definition of vigor itself.

The discovery of radioactivity led to the assertion that it was responsible for the alleged qualities of waters long reputed to have healing powers. The presence of radium emanation could actually be measured; and it gave a plausible basis for the claims of therapeutic virtue. In many instances, however, the radioactivity, though measurable, was so slight as to tax one's credulity with respect to any unusual reaction on the body. This has not deterred the quack from capitalizing a scientific fact and transforming it from minor into major significance. It has been urged that the curative virtues disappear in time from the water after its collection—a phenomenon that can perhaps be correlated with the fact that the emanation has a limited life and presently disappears. Hence there is plausibility for the belief that certain mineral waters lose their potency through aging.

There are other "healing springs," especially those containing iron, which exhibit their curative properties only when the water is taken fresh, yet show no radioactivity. Their potency has been ascribed to dissolved mineral salts. Baudisch and Welo[1] have pointed out that it is difficult to reconcile this explanation with the fact that in some cases, when the salts are separated from the waters and again redissolved, the new mineral water exhibits little and in many cases no healing action whatever. Studies recently completed by these chemists at the Rockefeller Institute for Medical Research indicate that certain iron compounds may undergo unique transformations on standing.[2] These varying properties evidently involve changes in the molecular configuration that are not expressed in the ordinary composition of the substances. It is demonstrated that some of the salts dissolved in water as they come out of the deep interior of the ground are in a particularly "labile configuration." Baudisch and Welo believe that in the aging process there is a rearrangement in space of the atoms, molecules, and groups of the latter. That this is not mere assumption is indicated by the demonstrable changes in properties. The still "active" iron ions have various properties in common with hemoglobin or blood iron; in fact, they may promote bacterial growth like the latter. The inactive or "aged" iron salts show none of these properties, which are so important biologically. Certain of their catalytic actions are speedily lost on standing.

These findings may presently give some insight into the mechanism of therapeutic action and its loss. Baudisch and Welo draw an analogy between certain functions of hemoglobin and the way that the active iron salts in fresh mineral waters may affect the life processes of body cells. In fact, they believe that such biologic potencies are not confined to the iron alone. Such speculations are interesting, but they must not be allowed to acquire unwarranted significance to the extent of exploitation by the unscrupulous. Experience teaches the danger of allowing fact and fancy to mingle too intimately—particularly when gullible persons are longing for health.

NIGHT BLINDNESS AND NUTRITION

It has become well established in recent years that certain disorders of the eye may be closely associated with malnutrition. The possibility of such an interrelationship was long suspected, but it remained for the more modern methods of investigation in the field of nutrition to replace conjecture by scientific demonstrations. An illuminating illustration is furnished by the experimental production of xerosis conjunctivae, or xerophthalmia, under conditions of diet in which there is a deficiency of vitamin A. The eye symptoms thereby observed in animals are identical in various respects with those noted in man; and they are relieved or averted, as the case may be, by similar therapeutic measures that depend on supplying the missing food factor.

There is another ocular disorder, night blindness, that has been ascribed to faulty diet among other explanations of its etiology. We are not referring here to congenital night blindness, or to the night blindness in retinitis pigmentosa or detachment of the retina, but to difficulty of adapting the faculty of vision to faint illumination. It is usually most pronounced when the eyes of the susceptible persons have been exposed to intense light, and becomes ameliorated after a period of rest in darkness. Several reasons have been cited in the past in favor of the assumption that this night blindness, or hemeralopia, may be associated with malnutrition. It has been discovered under conditions of presumably bad nourishment among prisoners, slaves, and sailors on long sea voyages. Observations of this sort are as recent as the period of the World War. An alternative view ascribes hemeralopia more exclusively to the effect of prolonged exposure to bright sunlight.

The fact that night blindness has been reported in certain patients suffering from xerophthalmia has been responsible for renewed attempts to ascertain the precise etiology of the hemeralopia. Holm[1] of the University Institute of Hygiene at Copenhagen has succeeded in demonstrating it experimentally in animals in which an incipient avitaminosis was induced by rations devoid of vitamin A. It is under such conditions of inadequate diet continued over a longer period that xerophthalmia develops in the same species. As in the supposed alimentary hemeralopia of man, there is in rats a delayed adaptation to darkness, but no lack of adaptation. The hemeralopia appears very early during the avitaminosis, as is also true in man. Whether at later stages of the disease an absolute hemeralopia with an essential limitation of the adaptation can develop has not been ascertained by Holm. However, his experiments indicate that the eyes of affected rats behave about like human eyes with respect to the boundary between night sight and day sight or, as he expresses it, with respect to the point at which the uvea begins to function.

An interesting concomitant of the experimentally produced hemeralopia of rats has just been demonstrated by Fridericia and Holm,[2] likewise at Copenhagen. Such animals, deprived of vitamin A under conditions that ultimately lead to the exhibition of xerophthalmia, are found to regenerate their visual purple after exposure to light more slowly than properly nourished rats do. This abnormality in the restoration of bleached visual purple seems to be somewhat specifically related to the lack of vitamin A; at any rate, it has not been found in malnutrition due to a lack of vitamin B. Whether the night blindness described by Holm depends on a defect in the function of the visual purple cannot be decided at present. The defect is observed only after the eyes have been exposed to the action of intense light. Night blindness behaves in the same way. Physiologists are still at sea regarding the purpose of the visual purple. It is no longer assumed to be required for the ordinary faculty of vision, although there are suggestions that twilight vision is dependent on the visual purple. In any event, the discovery of a number of striking ocular manifestations associated with a well defined dietary deficiency cannot fail to give impetus to progress in their identification and treatment. A good beginning has already been made.[3]

IRON IN THERAPEUTICS

The United States Pharmacopeia and the National Formulary contain sixty-four preparations of iron. The chemical fate and the therapeutic efficiency of medicinal iron, nevertheless, have long been uncertain, and debate has been proportionately voluminous. Cushny[4] well sums up what is known of the fate of medicinal iron preparations in the body, pointing out that they probably undergo changes in the stomach and then pass into the duodenum, from which the great bulk is carried on into the lower parts of the intestine. Some of the iron is absorbed by the epithelium and leukocytes in solid form and perhaps in solution and then is deposited in the spleen, where it may undergo some changes in form before being taken up by the blood and deposited in the liver and perhaps in the bone marrow. Cushny says:

> Where the supply of iron has been inadequate for the formation of hemoglobin, the originally inorganic iron is probably worked into higher forms and eventually into hemoglobin in the liver, and it seems likely that ferratin is one of the intermediate steps in this synthesis. When there is no deficiency of iron for the formation of hemoglobin, the liver slowly yields its store of iron to the blood, which carries it to the cecum and large intestine, by the epithelium of which

it is finally excreted. It is to be noted that the iron absorbed does not increase the amount of iron in the urine, bile or other excretions. The ordinary preparations of iron follow the same course in the tissues as the more complex compounds which exist in foods.

As may be seen, even this is qualified information. Actual chemical evidence has been difficult to get, because iron is normally present in the tissues, and the body utilizes quantitatively little of the iron that may be introduced therapeutically or in food.

It seems possible now, however, that much of the therapeutist's uncertainty may be cleared up. Williamson and Ets,[5] on the basis of experiments involving the use of large numbers of nearly identical animals over long periods of time under uniform conditions, have obtained results which merit consideration because of the controlled conditions under which they were secured. Inorganic iron, whether given by mouth, subcutaneously or intravenously, they found, is absorbed and may be found especially in the liver and spleen, but is not converted into hemoglobin. The futility of prescribing iron for anemia following hemorrhage is shown by the fact that animals made anemic by one or several large bleedings do not recover any more rapidly when inorganic iron is given. The efficiency of food iron seemed pronounced, and animals on a diet containing food iron recovered rapidly from hemorrhages that removed an amount of iron greater than exists in the entire body outside the blood. If the work of Williamson and Ets is confirmed, the next "Useful Drugs" may contain even fewer preparations of iron than the sixteen listed in the present new edition.

Current Comment

RELAXATION AND THE KNEE JERK

The prompt contractile response, or muscular "jerk," brought about by striking a stretched tendon is a physiologic phenomenon familiar to every one who is concerned with neuromuscular diagnosis. The widely used knee jerk test has been employed for half a century by clinicians. The responsive jerk has been regarded as the most refined measure available for judging the tone of muscle, and it is often used as an index of the functional condition of the nervous system. Early students of the reaction reported that the intensity of the knee jerk usually decreased during cerebral inactivity. It has recently been pointed out,[6] however, that during "relaxation" as ordinarily produced in clinical examinations the knee jerk is not diminished; in fact, it is usually increased. That this is due to actual failure to relax is shown by careful observations on persons specially trained in relaxation. In them the knee jerk really decreases parallel with advanced relaxation. In fact, by voluntary relaxation in the waking state one may attain a degree of neuromuscular tonus lower than that of light sleep, so that entire abolition of the knee jerk may occur in some cases. Jacobson and Carlson, who conducted the tests at the University of Chicago, assert that there is usually a "hang-over" of the effects of extreme relaxation, the jerk tending to remain diminished even after the person is instructed to cease relaxing; so that only reinforcement or moving the leg brings the response back to normal. Sometimes there is a diminution of the respiratory and heart rate. If it becomes clearly established that diminution of the knee jerk to the point of actual disappearance furnishes an objective criterion of the relative completeness of relaxation, the familiar test may acquire a clinical application not heretofore appreciated. This is especially true if, as has lately been suggested, an extreme degree of neuromuscular relaxation is effective in the therapy of certain nervous conditions.[7]

THE BASAL METABOLISM OF ORIENTALS

The measurement of the total metabolism, or the energy exchange of the body, affords an index of the food requirement from the quantitative point of view. The calory needs are modified by a variety of factors, among which muscular activity, size and the intake of food itself exercise pronounced effects. To determine whether disease also is involved it has become necessary to exclude the various extrinsic influences as far as possible before attempting any estimate of the fundamental transformations of matter in the organism. Hence the current practice of measuring so-called basal metabolism, that is, the energy exchange, during a period in which food is not being digested and in which voluntary activity is reduced to a minimum. The oxygen consumption is consequently ascertained in the person at complete rest in the postprandial condition. Even here it has been found that other factors inherent in the individual must be reckoned with. Size is obviously the foremost, but age and sex also have modifying influences on the intensity of the metabolism. It is accelerated in youth and relatively lower in women than in men. Investigators [8] who have studied Oriental women students in our American colleges have recently reached the conclusion that a racial effect in the direction of a lower metabolism must be recognized with the Chinese and Japanese. Apparently transplanted Orientals retain their inherited low metabolism, so that American and English physiologic standards should not be applied to them, particularly in the diagnosis of metabolic diseases. Corresponding with a basal metabolism averaging 10 per cent. below the best prediction standards, the Oriental young women studied showed a low pulse rate and a very low vital capacity, though their condition of nutrition seemed to be normal. Hence we may ask with Earle [9]: "Has the rush of Western civilization produced a higher metabolic rate? Is the low metabolic rate of the Chinese a physiologic expression of their more philosophic outlook on life?"

HEAT REGULATION AND WATER EXCHANGE

Evidence has accumulated in recent years to indicate that the concentration of the circulating blood varies in definite ways in response to changes in its temperature or in that of the environment of the body.[1] Dilution of the blood occurs when the physiologic circumstances demand a removal of heat from the organism. The action of many antipyretics involves a corresponding "mobilization" of water in the blood. The reverse response to cold has now been demonstrated by Barbour and Hamilton[2] of the University of Louisville to be due to an actual anhydremia rather than to any movement of blood cells that might simulate a concentration. The change is quick and reversible. Since the serum as well as the whole blood concentrates, the fluid movement out of the blood is clearly established, when external cold is applied to the exterior of the body. The Louisville physiologists[3] have established, further, that the tissues of the cooled surfaces contain more moisture than those of the uncooled. It appears, from the new analyses, that the fluid leaving the blood in the regulation of the body against a cold environment is diverted chiefly to the cooled skin, subcutaneous tissues and muscles. This results, according to Barbour and Hamilton, not only in a reduction of peripheral blood flow through concentration and a consequent saving of heat, but also in the production of an increased thickness of the insulating tissues. The more deeply lying parts are thus better protected from heat loss by the additional "padding" with water in the superficial layers.

Association News

THE DALLAS SESSION

Local Committee of Arrangements

Dr. E. H. Cary, Medical Arts Building, Dallas, Texas, on nomination of the Dallas County Medical Society, has been chosen chairman of the Local Committee of Arrangements. The names of other members of this committee and of its subcommittees will be published later.

Golf Special for Dallas Session

When the American Medical Association met in San Francisco in 1923, an "American Medical Association Golf Special" provided an unusual feature. The party left Chicago and made the trip to San Francisco by easy stages, playing golf each day in a different city. A similar special, limited to 125 physicians, will be conducted to the Dallas session. According to the schedule the train will leave Chicago, Sunday, April 11, at 6 p. m., arriving in Nashville, Tenn., Monday morning; golf will be played at Nashville. The train will leave that night and arrive the next morning in Biloxi, Miss., where the golfers will play; the next day golf will be played in New Orleans, the day following in Galveston and then in San Antonio, the train arriving in Dallas on Saturday, April 17. The trip also includes special arrangements for automobile trips, sea bathing and dancing for ladies and children who may accompany physicians as guests. The cost of the trip is $215, including round trip tickets from Chicago by special train and returning by direct route through St. Louis or Kansas City. Meals, compartment, green fees, caddy fees, automobile charges and tips are included in this charge. Complete information and application blanks may be secured from Dr. F. C. Warnshuis, Powers Theater Building, Grand Rapids, Mich.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Bacterial Rat Exterminators Forbidden.—The state board of health recently ruled to forbid the sale or exposure for sale in the state of any of several alleged rat exterminators, the efficiency of which depends on cultures of bacteria which may contaminate human food. Experiments conducted under the auspices of the state board failed to demonstrate any great efficiency in the so-called exterminators but showed that they might lead to the production of a chronic carrier state in rodents of bacteria which are known to cause food poisoning.

Mr. Aycock Was Fined.—Charles F. Aycock of the so-called Aycock Medical Institute, Los Angeles, was arrested, August 1, it is reported, on a charge of violating the medical practice act. He pleaded guilty and paid a fine of $100. Aycock claims to have protected himself by applying for a chiropractic license under which he could examine patients. According to Nostrums and Quackery, when Aycock was county treasurer of Boone County, Arkansas, he was arrested on a charge of embezzlement; released on bail; forfeited his bail by leaving the state but was later captured when about to sell a fake gold mine. It is further related that he was sentenced to the penitentiary for five years on a charge of embezzlement but was pardoned after one and a half years.

COLORADO

State Medical Election.—At the annual meeting of the Colorado State Medical Society, Colorado Springs, September 29-October 1, Dr. George A. Boyd, Colorado Springs, was installed as president; Dr. George H. Curfman, Salida, was elected president-elect; Drs. Edward Delehanty, Denver, Walter E. Hays, Sterling, Edward E. H. Munro, Grand Junction, and Lanning E. Likes, Lamar, vice presidents; Dr. Frank B. Stephenson, Denver, secretary; Dr. William A. Sedwick, Denver, treasurer, and Dr. Charles N. Meader, Denver, and Dr. Lewis H. McKinnie, Colorado Springs, delegates to the American Medical Association.

CONNECTICUT

Freshman Class at Yale.—From more than 400 applicants fifty-two students have been selected as freshmen in the Yale School of Medicine this year. According to Dean Winternitz one third of the class is from Connecticut and eighteen of them are Yale men. Those chosen for the class completed their undergraduate work at twenty-six colleges and universities.

Dr. Ruggles Goes to Yale.—Dr. Arthur H. Ruggles, director of the Butler Hospital, Providence, R. I., has obtained a year's leave of absence to accept an appointment as consultant in mental hygiene to the department of university health and as lecturer in psychiatry in Yale University School of Medicine for a period of one year. The university has also nominated Dr. Ruggles to the board of directors of the New Haven Hospital as psychiatrist to the hospital and dispensary. Dr. Ruggles served during the World War as consultant in neuropsychiatry and was decorated with the Croix de Guerre by the French government.

DISTRICT OF COLUMBIA

Increase in Medical Inspection Service.—An increase in the medical inspection service for the public schools of the District of Columbia was requested at a conference between General Lord, chief of the budget, and a special public health committee from the Monday Evening Club. Facts were presented to show General Lord that the school medical inspection service in Washington is far behind similar work in other large cities and that increased appropriations for this work are essential to the health of school children. The conference followed the receipt, Thursday, of authoritative information that the Budget Bureau had disapproved almost all of the increased appropriation which the board of education and the District commissioners had sought to improve the school medical service. Although budget officials refused to give assurance that the conference would result in a new decision to approve increased appropriations, Dorsey W. Hyde, Jr., president of the Monday Evening Club, declared that the interest shown by General Lord and his aides gave every hope that additional funds would be provided. The program outlined by the club at this conference has been endorsed by the Chamber of Commerce, the Board of Trade, Medical Society of the District, Instructive Visiting Nurse Society, Tuberculosis Association and many other organizations. Mr. Hyde declared, "we are not launching a fight on this matter, but simply want General Lord and other officials and the people of the District generally to know the facts in the case, confident that betterment will follow."

GEORGIA

Personal.—Dr. Lewis M. Gaines, Atlanta, has resigned as associate professor of neurology and psychiatry at Emory University School of Medicine, to devote his time to internal medicine and neurology.——Dr. John P. Kennedy has been reelected health officer of Atlanta for two years. The Fulton County Medical Society sent a delegation in appreciation of Dr. Kennedy's twenty-five years' service to endorse his reelection.

Society News.—At the recent meeting of the Fulton County Medical Society at the Academy of Medicine, Atlanta, Dr. Bertram H. Wagnon spoke on "Granuloma Inguinale Treated by Intravenous Injections of Tartar Emetic"; Dr. William R. Smith reported a case of "Perthes' Disease."——Brooks County Medical Society was recently host to the Thomas and Lowndes County medical societies at the Quitman County Club, Quitman. Among the speakers were Dr. Frank K. Boland, president of the Medical Association of Georgia; Dr. Joseph A. McGarity, Atlanta; Dr. Charles W. Roberts, Atlanta; Dr. John T. King, Thomasville, and Dr. Charles H. Watt, Thomasville.

ILLINOIS

Society News.—Dr. Arial W. George, Boston, will address the Central Illinois Radiological Society, Quincy, October 12, on "The Present Status of the Gastro-Intestinal Examination by Roentgen Ray." A dinner and reception will be given preceding the meeting.

Scarlet Fever at Elgin.—Elgin was reported to have had twenty-four cases of scarlet fever, September 28, making a total of 111 cases thus far this year, which exceeds the records for the last five years. While there were only forty-eight cases of scarlet fever in Elgin last year, there were four deaths. There have been no deaths in 1925 from scarlet fever.

Diphtheria Trends Upward.—Since September 1 the prevalence of diphtheria in Illinois has doubled; about 100 cases are reported each week. This is the highest incidence since April and is double the average incidence in August; until late in the winter, the state commissioner of health says, an average of from 150 to 200 cases will be reported a week if the incidence runs true to form. Last year diphtheria caused 470 deaths in Illinois, most of the victims being children under 6 years of age. The state department of public health distributes antitoxin and toxin-antitoxin gratuitously to all citizens of the state who need and desire it.

Chicago

Dr. Coulter in New Position.—John M. Coulter, Ph.D., for many years head of the department of botany at the University of Chicago, began his work as a member of the staff of the Boyce Thompson Institute for Plant Research at Yonkers, N. Y., October 1. The institute which was founded last year by Colonel Thompson is devoted especially to the study of diseases of plants and flowers.

Society News.—The first fall meeting of the Chicago Ophthalmological Society will be held at the Hotel Sherman, October 19; there will be a dinner at 6:30 as an informal reception for members of the American Academy of Ophthalmology and Otolaryngology. The scientific program will include discussions on "The Motor Anomalies of the Eye," and visiting members of the American Academy are invited to participate.——The first fall meeting of the Chicago Roentgen Society will be, October 9, at the Virginia Hotel. Dr. Arthur U. Desjardins, Rochester, Minn., will speak on "Radiotherapy at Low and Moderate Voltages," and Dr. Carroll E. Cook will report a case of osteitis deformans associated with osteogenic sarcoma.——Dr. Arthur J. Cramp, director, Bureau of Investigation, American Medical Association, will speak before the Chicago Laryngological and Otological Society, Hotel Sherman, October 19, on "Fake Aids for Hearing," illustrated by lantern slides, and Harvey Fletcher, head of the research department, Bell Telephone Laboratories, on "Interesting Data on the Improved Audiometer."

INDIANA

State Medical Election.—At the recent annual meeting of the Indiana State Medical Society, Fort Wayne, Dr. Charles N. Combs, Terre Haute, was elected president; Drs. Herman M. Baker, Evansville, Donald C. McClelland, Lafayette, and Angus C. McDonald, Warsaw, vice presidents; Dr. William A. Doeppers, Indianapolis, treasurer, and Drs. George F. Keiper, Lafayette, Albert E. Bulson, Jr., Fort Wayne, and David Ross, Indianapolis, delegates to the American Medical Association. The next annual meeting will be at West Baden in 1926.

KENTUCKY

Antirat Campaign.—Dr. Jesse I. Whittenberg, Louisville, is chairman of a committee, it is reported, of 119 physicians (one from each county in the state) and other members which will work in cooperation with the state board of health in a campaign to decrease the rat population of the state. It has been estimated that there are 10,000,000 rats in the city of Louisville.

Alumni Meeting.—The Louisville Alumni will hold their annual reunion and dinner in connection with the meeting of the Southern Medical Association, November 11, at 7 o'clock in the Adolphus Hotel, Dallas, Texas. Notices of attendance should be sent during October to the Dean, School of Medicine, University of Louisville, 101 West Chestnut Street, Louisville, and after November 1 to Dr. Stuart Graves, Adolphus Hotel, Dallas. Tickets will be on sale at the alumni window at registration headquarters, Dallas.

MASSACHUSETTS

Testimonial to Dr. Kelley.—At a meeting called, September 28, in Boston, the executive committee of the Boston Health League which comprises thirty health and welfare agencies, adopted a testimonial as a tribute to the work of the late Dr. Eugene R. Kelley, commissioner of health of Massachusetts, in which, it was said that Dr. Kelley gave his life for the betterment of his fellowmen and that in spite of many difficulties which his position presented, he maintained a spirit of ardent optimism, insisting on the close relationship of public health work to the private practice of social work.

Professor Coolidge Retires.—Dr. Algernon Coolidge, for fourteen years professor of laryngology at Harvard University Medical School, Boston, has retired from that position and been elected professor emeritus. Dr. Coolidge has been associated with the Harvard Medical School for thirty-two years. The appointment of Lemmie R. Cleveland, of Johns Hopkins University, Baltimore, as assistant professor of protozoology at Harvard University Medical School, was also announced, and that of Dr. Fred W. Morse, Jr., as instructor in bacteriology, Dr. Dwight L. Sisco as assistant in industrial medicine and Dr. Reginald M. Atwater, instructor in epidemiology.

MINNESOTA

Business Bans Medicine Shows.—At the request of the business and professional men of the city of Hibbing, a ban has been placed on medicine shows in that city and no more permits to them will be issued. Hibbing has a population of more than 15,000.

Meeting of Resident Physicians.—The annual meeting of the Association of Resident and Ex-Resident Physicians of the Mayo Clinic will be at Rochester, Minn., October 19-21.

A program may be obtained from Dr. Gilbert J. Thomas, 1009 Nicollet Avenue, Minneapolis.

Society News.—At the annual meeting of the Minnesota Academy of Medicine, September 9, Dr. Henry L. Ulrich, Minneapolis, was elected president, Dr. Frank E. Burch, St. Paul, vice president, and Dr. John E. Hynes, Minneapolis, secretary-treasurer (reelected). It was decided to accept the invitation of Dr. Edward S. Judd to hold the November meeting at Rochester.

Dr. Beard Appointed Field Secretary.—The board of directors of the Hennepin County Public Health Association unanimously invited Dr. Richard O. Beard to accept the field secretaryship of the association on a part-time basis. Dr. Beard, who recently retired from active teaching work at the University of Minnesota, has accepted the appointment. He will continue to devote the major part of his time, however, to the direction of the committee on endowment and building funds of the University of Minnesota School of Medicine (The Journal, April 18, p. 1190).

NEBRASKA

Personal.—Dr. Aura J. Miller, Boston, has arrived in Omaha to succeed Dr. John Jay Keegan as associate professor of clinical pathology in the University of Nebraska College of Medicine. The vacancy was due to the appointment of Dr. Keegan as dean of the medical school.——Dr. Claude W. Mason, formerly of Omaha and for nineteen years a medical missionary in the Orient, has returned to Omaha to engage in practice.

Society News.—A joint meeting of the Third and Seventh Councilor District Medical Societies was held at Beatrice, September 10, at which Drs. Palmer Findley, Arthur D. Dunn and Charles W. Pollard conducted dry clinics and spoke on "Precancerous Lesions of the Uterus," "Gastric Physiology and Symptomology," and "Toxemia of Pregnancy," respectively. There was a banquet at the country club in the evening.——At the August 28 meeting of the Eleventh Councilor District Medical Society, North Platte, Dr. Daniel T. Quigley, Omaha, the guest of honor, spoke on "Cancer," illustrated by lantern slides.

NEW YORK

Meeting of Committee on Tuberculosis and Public Health.—The semiannual meeting of the New York State Committee on Tuberculosis and Public Health will be at the Hotel Biltmore, New York, November 19-20. The committee will meet with the advisory Council of the Milbank Memorial Fund which convenes for the purpose of considering the progress of the health demonstrations being made at Syracuse and in New York City under the auspices of the fund. The New York City tuberculosis conference will also be held at the same date and place.

New York City

Macfadden's Americanism Protective League.—One of the latest fads of Bernarr Macfadden is the Americanism Protective League, which is circularizing the public with forms addressed to state legislators asking them to oppose the passage of a medical practice act. Macfadden is said to have organized the league.

Cancer Institute Opens.—The Brooklyn Cancer Institute in the old Cumberland Street Hospital building will open next week with Dr. Charles A. Brown in charge. The board of estimate has approved an appropriation of $15,000 for salaries of the technician and nursing staff. In about another month when reconstruction has been completed, bed cases will be received.

Wesley M. Carpenter Lecture.—Dr. Lewellys F. Barker, Baltimore, will deliver the Wesley M. Carpenter Lecture at the New York Academy of Medicine, Thursday evening, October 15, 8:30, on "The Management of Neurotic Patients." Dr. Carpenter was formerly corresponding secretary of the New York Academy of Medicine and editor of the *New Orleans Medical and Surgical Journal.* In his will he left $5,000 to the academy for an annual lecture.

Dr. Giddings Appointed Superintendent.—The president of the Reconstruction Hospital announces that Dr. Emanuel Giddings, New York, has been appointed superintendent. Dr. Giddings was physician in charge of the Willard Parker Hospital and of the Riverside Hospital; he served as a major with the One Hundred and Second Engineers in France and is now lieutenant-colonel of the Three Hundred and Fiftieth Medical Regiment. The Reconstruction Hospital is devoted to the care and treatment of industrial accidents and diseases.

Personal.—Dr. Richard H. Meade, Jr., has been appointed on the staff of the St. James Hospital, Anking, China, by the Department of Missions of the Protestant Episcopal Church.——Dr. Robert T. Frank, formerly of Denver, Colo., has been appointed gynecologist to Mount Sinai Hospital, New York.——Dr. Alexis Carrel, Rockefeller Institute for Medical Research, returned to New York, September 23, from his annual vacation in France.——Dr. Joseph E. Burns, Goldston, N. C., has been appointed house surgeon at the Willard Parker Hospital.——Dr. Isaac Glassman has been appointed roentgenologist to the Metropolitan Hospital.

Report of East Harlem Health Center.—A recent report called "The House that Health Built" covers the first three years' work of the East Harlem Health Center, in which all local health agencies combined to raise the standards of health in the East Harlem District and to decrease the death rate. Public, private, religious and nonsectarian agencies joined in this plan. From 1921 to 1923 the death rate in the East Harlem District decreased 23 per cent., it is said, while for the city as a whole it decreased only 20 per cent. The long list of agencies that participated in this campaign have combined to conduct neighborhood health demonstrations, prevent tuberculosis, raise nursing standards, give better infant care and instruction in nutrition to children and parents. The campaign has reached 193,055 persons.

Progress of Presbyterian Hospital Fund.—Dean Sage, president of the Presbyterian Hospital, announced, October 2, that $6,250,000 of the $7,000,000 building fund for the new Presbyterian Hospital had been received to date. A committee was formed to speed the raising of the remainder before winter comes. Mr. Sage announced that the two $25,000 gifts made last spring by Miss Annie B. Jennings and Mrs. Walter B. James were to establish two five-bed medical wards as memorials to "the distinguished services of Dr. Walter B. James to the Presbyterian Hospital and to medical science." When the Uptown Medical Center Association, Inc., formed to collect $400,000 with which to build a floor in the hospital and to cooperate in any way possible in its construction, met October 3, it had raised $156,000. The first unit of the new Medical Center is now under construction.

New Campaign to Eliminate Diphtheria.—Dr. Frank J. Monaghan, health commissioner, has announced a new campaign to eliminate diphtheria in the Bellevue-Yorkville district, starting this week, to be conducted by the Milbank Memorial Fund in cooperation with the department of health. It will be in charge of Dr. Leverett D. Bristol, representing the former organization, and Drs. William H. Park and John Oberwager of the health department. All private physicians in the district will be supplied with antitoxin free of charge. Children will be immunized against diphtheria at stations conducted by the health department at 306 Avenue A, 248 East Thirty-Second Street, 241 East Fortieth Street and 322 East Fifty-Ninth Street. The Metropolitan Life Insurance Company has volunteered to distribute in the district 50,000 leaflets on diphtheria published by the Milbank Foundation. The object in distributing antitoxin to private physicians is to enable them to administer it early in the disease.

NORTH CAROLINA

Free Orthopedic Clinics.—The first of the free orthopedic clinics for cripples to be given by the State Division of Rehabilitation was held in the office of the Cumberland County Health Department at Fayetteville by Dr. Alonzo H. Myers, Charlotte; it included seven counties. Clinics are to be held by leading orthopedic surgeons residing in the zones into which the state will be divided. The service is free, the expenses being paid by some local organization, while free hospital beds have been provided by other organizations for indigent patients. H. L. Stanton, state director of rehabilitation, is visiting the county medical societies to secure their cooperation.

Personal.—At the quarterly meeting of the executive committee, state board of health, Raleigh, September 30, Dr. Joseph Howell Way, president of the board, presented, on behalf of the members, two pieces of silver to Dr. Watson S. Rankin, former secretary of the board, as a token of appreciation of his service.——The president of the State Normal College of Cullowhee, Jackson County, announces the arrival of Dr. Luther B. Newman, Knoxville, Tenn., to assume the duties of health director and resident physician to the college. Dr. Newman will also conduct the classes in hygiene and physiology, and arrange for filing a complete physical examination of each student in accord with the recommendations of the state board of health.

NORTH DAKOTA

Dr. French Resigns.—Dr. William J. French, director of the child health demonstration being conducted by the American Child Health Association at Fargo, has resigned and will go to Austria, according to the *Journal-Lancet*, to conduct similar work; he will be succeeded by Dr. William De Kleine, now in charge of the child health demonstration conducted at Mansfield, Ohio.

OHIO

Advertising of Life Extension Institute Refused.—At a meeting of the Council of the Ohio State Medical Association, Columbus, September 13, communications from the Life Extension Institute were discussed, and it was voted to instruct the publication committee of the state association not to accept advertising from that institute.

Hospital Survey.—The hospital facilities of Cincinnati were recently surveyed by a representative of the Helen S. Trounstine Foundation at the request of the building fund committee of the Community Chest. It was found that there are eighteen private hospitals with 2,110 beds in Cincinnati, three municipal hospitals with 1,140 beds and twelve proprietary hospitals with 355 beds. Among the seventeen recommendations in the report are that a program be worked out for the care of convalescent patients discharged from the hospitals; that a committee of members of medical staffs of institutions be organized to elevate the standard of medical work in chronic diseases, and that in order to carry out these and other recommendations and afford an opportunity for joint planning, a hospital council be formed representing the hospital superintendents and trustees, the academy of medicine, and the public.

PENNSYLVANIA

Scholarships for Postgraduate Study.—Scholarships on the Oliver-Rea Foundation, the income of which is used for graduate study in medicine at the New York Post-Graduate Medical School and Hospital, are available. The scholarships are of no fixed value, the usual amount granted an applicant being not over $500; one-half of the tuition is paid in prolonged courses of instruction. The committee in charge is Drs. James F. McKernon, William D. Cutter and Ludwig W. Kast. Inquiries should be addressed to the Dean, 301 East Twentieth Street, New York City. Preference of scholarships will be given to applicants who are residents of Pennsylvania.

Philadelphia

Hundreds of Students Turned Away.—When the University of Pennsylvania, Philadelphia, had completed, October 3, 87 per cent. of its registration of full-time students it had then been unable to admit, according to the New York *Times*, about 2,200 students who sought admission. Full-time registration in the school of medicine amounted to 458 and in the dental school to 516.

Joint Meeting of Pediatric Societies.—The New England Pediatric Society, the Pediatric Section of the New York Academy of Medicine, and the Philadelphia Pediatric Society held a joint meeting at various hospitals in Philadelphia, October 10. There was a symposium on "Post-Tonsillectomic Pulmonary Abscess" by Drs. Edwin E. Graham, Willis F. Manges, Chevalier Q. Jackson, Louis H. Clerf and Gabriel Tucker. Dr. Eugene L. Opie, among others, spoke on "Newer Studies in Tuberculosis in Children." There was a luncheon at the Children's Hospital, an excursion to the Pennsylvania Training School for Feeble-Minded Children at Elwyn, and a dinner in the evening at the Hotel Rittenhouse.

Personal.—Dr. Helen Ingleby, London, England, has arrived to take up her duties as professor of pathology at the Woman's Medical College of Pennsylvania, succeeding Dr. Maude Abbott, who has returned to McGill University, Montreal.——Dr. William Pepper, Jr., dean, University of Pennsylvania School of Medicine, has been granted leave of absence until Christmas to go to England, France and Italy to inspect medical schools.——Dr. Francis C. Grant, associate in surgery, University of Pennsylvania School of Medicine, and instructor in surgery in the Graduate School of Medicine, has been granted leave until June to do special work at the Brighton Hospital, Boston.——Dr. Arthur P. Keegan assumed the duties of coroner's physician, October 1, succeeding Dr. Richard D. Burke.

TENNESSEE

Broader Service in State Health Department.—The state department of public health recently moved to new quarters in the Capitol Annex in the Tennessee War Memorial Building, and rearranged its activities to make them more effective. A division of epidemiology has been organized for the special study and control of preventable infectious disease; Dr. Edward A. Lane is superintendent of this division. The division of maternal and infant hygiene has been expanded and named the division of child hygiene and public nursing to embrace all work associated with the child from the prenatal period through school age. The work of the division of venereal disease control has been "scattered" among other divisions whose work has a bearing on this problem and a division of public health education created to take its place. In addition a whole-time director and laboratory service was instituted the early part of this year and an additional sanitary engineer secured. The state department, under the leadership of Dr. Eugene L. Bishop, comprises the divisions named and the division of general administration, division of vital statistics and the division of sanitary engineering. The personnel comprises twenty-eight persons, seven of whom are physicians.

TEXAS

Sanitary Survey of Rock Island Railroad.—The Rock Island Railroad has planned a campaign for eliminating malaria along its right of way through Arkansas, Louisiana, Oklahoma and Texas, using measures which have been successful in the antimalaria campaign of the Cotton Belt Line. At the same time a survey of the Rock Island will be made to eliminate other insanitary conditions.

Society News.—The members of the Coryell County Medical Society, Gatesville, and their wives held a dinner at Raby Park, August 6, and in the evening invited the public to a meeting which was addressed by Dr. Niel D. Buie, Marlin, councilor of the twelfth district, on "The Protection of the Child," and Dr. Arthur C. Scott on "The Prevention and Treatment of Cancer."——Dr. Robert B. Giles addressed the Dallas County Medical Society, August 13, at the Dallas Baby Camp, on "Clinical Recognition of Coronary Obstruction."——At the August meeting of the Potter County Medical Society the advertising and editorial committee was authorized to publish a roster of the society in the newspaper and to aid in the campaign against irregular practitioners, now under way, by the state medical association.——Dr. Leon H. Martin, recently appointed director of health of Fort Worth, addressed the Tarrant County Medical Society, August 4, on "The History of Public Health in Fort Worth," and Dr. E. H. Bursey, August 18, on "Splenectomy as a Cure for Purpura Hemorrhagica."

VERMONT

Gift to University.—By the will of the late Mrs. Emma H. Slade, New York, the University of Vermont received a trust fund of $50,000 for a memorial. The will provides also that the residuary estate be divided into three parts to be held in trust, and that upon the death of the first two beneficiaries the funds so represented shall be paid to the Massachusetts General Hospital, Boston, for whatever use the trustees may deem best, and that if the principal of the first two trusts does not amount to $25,000, a sufficient sum to make up the difference shall be given to the hospital on the death of the third beneficiary and the remainder of the third trust be given to the Fordham Home for Incurables, New York.

State Medical Meeting.—The one hundred and twelfth meeting of the Vermont State Medical Society will be at the Armory, St. Johnsbury, October 15-16, under the presidency of Dr. Eugene A. Stanley, Waterbury. Col. Edwin A. Tobin, M. O., R. C., will deliver the vice president's address on "Organization of Medical Reserve Corps of the U. S. Army." Among others, Dr. Orrin Sage Wightman, New York, will speak on "The Significance and Value of the Periodic Health Examination"; Dr. William L. Aycock, Burlington, associate in preventive medicine and hygiene, Harvard University Medical School, Boston, "Epidemiology of Acute Anterior

Poliomyelitis," and Dr. William C. Woodward, executive secretary, Bureau of Legal Medicine and Legislation, American Medical Association, "Present Status of Organized Medical Defense Against Malpractice Suits." The banquet will be Thursday evening at 8 o'clock at the St. Johnsbury House. There will be a symposium Friday on headache, in which Dr. Roger I. Lee, retired professor of hygiene of Harvard University; Dr. William Jason Mixter, Boston; Dr. George A. Waterman, Boston; Dr. Daniel Crosby Greene, instructor in laryngology at Harvard University, and Dr. George S. Derby, Williams, professor of ophthalmology at Harvard University, will participate.

WEST VIRGINIA

Fifty Physicians Fined.—During the last summer, more than fifty physicians in West Virginia were fined in justices' courts on complaints made by the U. S. Census Bureau for failure promptly to report births. In February there were 621 births reported to the Bureau of Vital Statistics one or more months late; in March, 790; in April, 1,029; in May, 1,374, and in June, 1,059, that were one or more months late. To correct this tendency, two field inspectors were placed on duty in May with orders to arrest outstanding cases of those who were responsible for the late reports.

WISCONSIN

Damages for Stream Pollution.—The supreme court of Wisconsin has awarded a realty company $50,000 damages for flooding of a farm and the creation of a public nuisance in the waters of Honey Creek by the discharge of raw and partially treated sewage into the stream by the city of West Allis and ordered that city to abate the nuisance within sixty days. In denying the appeal of the defendant the court emphasized, according to the chief chemist of the sewerage commission of Milwaukee, that no municipality has the right to pollute a natural watercourse to the detriment of lower riparian owners, and that a city or corporation which discharges sewage into a natural watercourse must purify its sewage irrespective of the cost so that it will cause no injury to lower riparian rights.

HAWAII

Personal.—Dr. Frederick E. Trotter, president of the board of health of Honolulu, has been sent by the Pan-Pacific Union as the official delegate of Hawaii to the conference of the Far Eastern Association of Tropical Medicine, to be held at Tokio, October 11-November 1.

GENERAL

A Secretary's Courtesy Rewarded.—A physician's secretary in Milwaukee observed that patients waiting frequently show an interest in health matters generally. She undertook to speak to such patients, at an opportune time, about *Hygeia*, and found that they did not know where to obtain a good health magazine and that they appreciated her courtesy. In this way, Miss Evelyn Gary obtained eighty-three subscriptions to *Hygeia* without interfering in any way with her office work.

First Meeting of Commission on Medical Education.—The commission, initiated by the Association of American Medical Colleges and participated in by the Rockefeller Foundation, the Carnegie Foundation and the American Medical Association, to conduct a comprehensive survey of medical education in the United States (THE JOURNAL, July 4, p. 46) will hold its first meeting in Buffalo at the Hotel Statler, Monday, October 19, for the purpose of electing officers, effecting a permanent organization and outlining the plan to be pursued in the conduct of this work.

Agamede Medal of the Women's Foundation for Health.—This foundation has announced the establishment of the Agamede Gold Medal, which will be awarded annually to that woman citizen of the United States who has performed the most distinguished service during the last year in advancing the health and happiness of American women. The winner of the medal need not be a scientist, the only prerequisite being that she shall have performed some signal service in this field. Agamede was a Grecian woman mentioned in Homer's "Iliad," the first woman other than mythologic characters who brought health and happiness to fellow human beings. Dr Martha Tracy, dean of the Woman's Medical College, Philadelphia, is president of the Women's Foundation for Health and Mrs. Drury W. Cooper, Montclair, N. J., secretary; Dr. Lenna L. Meanes is medical director, and Essie D. Hathaway, executive secretary of the foundation, 370 Seventh Avenue, New York. The final award of the medal will be made by a committee of nationally known men and women.

Health Survey of Eighty-Six Cities.—The American Child Health Association will issue, October 12, a report on a health survey of eighty-six cities undertaken late in 1923 and completed in June, 1924. The introduction describes how the survey was done; section two gives the practices in the different lines of health work in these cities; section three contains sketches of each city and section four suggestions for the organization of health work in a city of 50,000. It was found that the average cost of the health departments in these eighty-six cities, ranging from 40,000 to 70,000 population, is 42 cents per capita, the average salary of the full-time health officer in these cities $3,404, that sixteen of these cities have no boards of health, that only forty-five had a full-time health officer, and that the full-time employees varied from one in one city to more than twenty in five cities; another one had no full-time employees in its health department, having four persons who devoted a total of six hours a week to health matters. Toxin-antitoxin is being used in forty of the cities to immunize children against diphtheria. The reporting of tuberculosis to health authorities is "inexcusably lax" and in seventeen cities the number of deaths reported actually exceeded the number of cases. Forty of the cities surveyed have established prenatal clinics under the guidance of physicians and five cities have mothers' conferences. There were infant welfare clinics in eighty of the eighty-six cities; sixty-five cities reported having added courses in health to their school curricula; eighteen cities had had epidemics of communicable disease traced to the milk supply in the last five years; only eight cities protected their entire milk supply by adequate pasteurization and twelve others pasteurized more than 90 per cent. of their supply. Since completing the field work of this survey, the American Child Health Association has prepared a community health program which it considers practical for a city of 50,000 and which it intends for the use of public health administrators. The report considers that the greatest needs now are well trained health officers who give their undivided attention to health work, the standardization of methods, some thought in explaining health work to the public and better team work among public and private health agencies.

Association of American Medical Colleges.—At the thirty-sixth annual meeting of this association, Charleston, S. C., October 26-28, at the Fort Sumter Hotel, the presidential address by Dr. Hugh Cabot, dean, University of Michigan Medical School, Ann Arbor, will be "Should Medical Education Be Importantly Recast?"; Dr. William Keiller, dean, University of Texas School of Medicine, will speak on "The Claims of the Fundamental Subjects"; Dr. Charles F. Martin, dean, McGill University Faculty of Medicine, on "The Relative Value of Subjects in the Medical Curriculum"; Marion R. Trabue, Ph.D., director, Bureau of Educational Research, University of North Carolina, on "Increasing the Usefulness of Examinations"; Charles E. Chadsey, Litt.D., dean, College of Education University of Illinois, "Technic of Teaching as Applied to Medical Teaching"; Dr. John S. Rodman, secretary-treasurer, National Board of Medical Examiners, "Impressions on Medical Teaching Gained from Ten Years' Experience with National Board Examinations"; Dr. Carl A. Hamann, dean, Western Reserve University School of Medicine, "The Teaching of Surgery"; Chester J. Farmer, A.M., professor of chemistry, Northwestern University Medical School, "The Teaching of Biochemistry"; Karl F. Meyer, Ph.D., professor of bacteriology, University of California Medical School, "The Teaching of Bacteriology in the Medical Curriculum"; and Dr. Charles C. Bass, dean, Tulane University of Louisiana School of Medicine, "The Teaching of Practical Clinical Laboratory Work in the Undergraduate School."

There will be practical demonstrations in teaching at the Medical College of the State of South Carolina, Tuesday morning, and in the afternoon a round table conference in which the discussions will be opened by: Drs. Irving S. Cutter, dean, Northwestern University Medical School, Chicago; Charles P. Emerson, dean, Indiana University School of Medicine; Oskar Klotz, Toronto University Faculty of Medicine; Basil C. Harvey, University of Chicago; William F. R. Phillips, Medical College of the State of South Carolina; G. Canby Robinson, dean, Vanderbilt University School of Medicine; William H. Goodrich, dean, University of Georgia Medical Department; John W. Moore, University of Louisville School of Medicine, Kentucky, and Albert P. Mathews, Ph.D., University of Cincinnati College of Medicine. The business session will be Wednesday morning. Northwestern University Medical School, Chicago, has proposed an amendment to Article 3, Section 5, to the effect that the annual dues shall be $100.

FOREIGN

Malaria Committee Concludes Its Tour.—The *Siglo Médico* of Madrid states that the malaria committee of the League of Nations, which has been studying conditions in Spain after its tour of investigation in Russia and Palestine, concluded its labors, September 7, the members returning to their homes. The last gathering in Spain was at a banquet tendered the committee at Barcelona by the state and municipal authorities and others.

Outbreaks of Plague.—Six cases of plague were reported in Egypt during the week ending August 12, making a total of ninety-six cases in that country reported this year.——A member of the crew of the S. S. *Anatolia* sick with plague was removed from the ship at Piraeus, Greece, August 8. The *Anatolia* had come from Alexandria, Egypt.——During the period July 16 to August 15, ninety-one rats trapped at Guayaquil, Ecuador, were found to be plague infected.——A plague infected rodent was reported at Paauhau, Hawaii, August 12.

Personal.—Dr. J. F. F. Babinski, Paris, has been appointed honorary professor of neurology at the University of Vilna.——Prof. L. E. Barnett is to preside at the Second Medical Congress of Australia which is soon to convene at Dunedin, New Zealand.——Dr. Pierre Lépine, has been appointed professor of internal medicine at the American University of Beyrouth.——The *Bruxelles-médical* gives the names of seven young confrères who have won scholarships for study in the United States, Brutsaert, De Guchteneer, d'Hoenens, Eeman, Morelle, Radelet and Verhoogen.——The Elia de Cyon prize of the Academy of Sciences at Bologna has been awarded this year to Prof. H. Fredericq of Liége for his works on "The Humoral Mechanism of the Action of Various Heart Remedies in Coldblooded Animals." The second prize was given to Dr. L. Lotti for his research on plethysmography. The title of his work was "The Vasomotor Reflexes in Young Infants and the New-Born."

Deaths in Other Countries

Sir **Alan Reeve Manby**, royal physician to the late King Edward and to King George, September 29, at London, England, aged 78.——Dr. **A. M. Centeno**, professor of pediatrics, Buenos Aires, formerly president of the Argentine Medical Association and first president of the Pediatrics Society, aged 62.——Dr. **C. Homem de Mello**, chief of staff of the hospital for mental disease at S. Paulo, aged 63.——Dr. **M. Simmonds**, prosector and director of the Pathologic Institute at Hamburg from 1882 to 1924.——Dr. **L. Merk**, professor of skin and venereal diseases, at Innsbruck.——Dr. **J. Berdez**, professor of materia medica, Lausanne.——Dr. **W. Krebs**, Zurich, aged 79; he practiced in a rural district and made all his rounds on foot for the love of nature and for health.——Dr. **Bacquelin**, Nevers, another victim to the professional use of the roentgen rays, aged 56.——Dr. **Clotilde Mulon**, Paris, on the staff of the *Nourrisson*, founder and director of an infant's asylum.——Dr. **H. W. Freund**, formerly professor of obstetrics at Strasbourg, aged 66.

CORRECTIONS

Dr. De Eds Is Assistant Professor.—Floyd De Eds, Ph.D., has been appointed assistant professor of pharmacology instead of professor at Stanford University Medical School, San Francisco (The Journal, September 28, p. 980).

Smallpox Statistics.—In a current comment on this topic it was stated that the United States held first place among all nations for the greatest number of cases of smallpox. The figures quoted were taken from a bulletin issued by the American Association for Medical Progress. This association now calls attention to the fact that the number of cases for European Russia should have been the total for all Russia, and that the figure for India represented deaths and not cases. According to these corrections, the United States would have the second largest number and not the first.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Sept. 19, 1925.

Bernard Shaw on the Irish Medical Controversy

The acute controversy in Ireland which has followed the decision of the government to establish a separate medical register has been described in previous letters. In characteristic fashion, Mr. Bernard Shaw, who is always entertaining in his advocacy of the paradoxical, has plunged into the controversy. In a letter to the *Irish Times* he has given his countrymen advice: "The Free State government will, I hope, carry through its decision to rescue Ireland from the disastrous control of that despised and self-disgraced trade union, the British medical council. At present unregistered practitioners charge and are willingly paid higher fees than registered ones because they have acquired the modern technics which the council boycotts and persecutes. The most famous manipulative surgeon in England, knighted for his services, being unregistered, is denounced and ostracized as a quack by men of whom some, though registered as competent surgeons, are hardly dexterous enough to manipulate their own shoe laces. The council avenges itself for the public slight of the knighthood by threatening to repeat its old exploit of striking off the register any one who acts as an anesthetist to him. Now comes the serious question, Will an Irish medical council prove any better? Certainly not, if the Irish government acts as stupidly and ignorantly as the English. In President Cosgrave's otherwise sensible statement there is one terrifying phrase, 'a self-controlled medical profession.' A self-controlled medical profession is a conspiracy against the laity. The profession has a direct pecuniary interest in keeping us ill and mutilating us, and needs the sternest disinterested control. The health officer is the only sort of physician who should be trusted in a properly constituted council. Let the new Irish medical council be accessible to practicing physicians in the capacity of consultants and assessors only and consist exclusively of representatives of disinterested scientific culture and the laity. If this condition is complied with, an Irish degree will soon stand higher than an English one."

Of course, the answer to this tirade is that the medical council—whatever may be said of some other medical bodies—has nothing to do with trade unionism. Its function is to control education and insure proper standards for admission to the profession and maintain professional discipline. It, indeed, protects the laity against the profession. It cannot extend any recognition to unqualified persons, as it would be stultifying the very purposes for which it exists. For the same reason it cannot allow qualified physicians to administer anesthetics for unqualified practitioners. However skilful the particular bonesetter mentioned above may be, if the position which Mr. Shaw desires for the unqualified generally were granted, it would mean the flood of quackery to the detriment of the public. Moreover, this is a free country in which any one can practice medicine as long as he does not pretend to be qualified. As regards the law, he suffers from only two disabilities—not of great moment. He cannot sue for payment for medical services, and if a patient dies under his treatment he cannot grant a death certificate, and therefore a coroner's inquest automatically follows. Beyond restraining qualified persons from administering anesthetics for the unqualified, the council in no way does or can interfere with unqualified practitioners. Shaw therefore misrepresents when he says that they are persecuted by the council.

Lunacy Report

The annual report for 1924 has been issued by the board of control (the body appointed by the government to control lunacy administration). It states that need for additional accommodation for mental defectives is acute, and the lack of suitable accommodation is hampering the operation of the mental deficiency act. The accommodation recommended is the villa system, as this allows better classification and training, and secures for the defectives happier lives than institutions of the barrack type. An increase in facilities for early skilled treatment of mental disorder without certification is recommended as a means of reducing the number of cases of insanity of confirmed character. The increasing frequency with which persons mentally ill submit themselves to treatment in registered hospitals and licensed houses is considered gratifying. Jan. 1, 1925, the number of insane under care in England and Wales was 131,551, an increase of 1,217 on the number of Jan. 1, 1924. But this is considered to have no necessary connection with the incidence of mental disorders in the general population.

The Medical Treatment of School Children

The board of education has issued new special regulations made under the education act. Each child in a public elementary school must be medically examined on admission, and on attaining the age of 8 and of 12 years. Local authorities must make arrangements for (*a*) following up cases of defect found in the course of medical inspection, (*b*) the detection and prevention of uncleanliness, and (*c*) the medical treatment of defects of eyes and teeth, minor ailments and enlarged tonsils and adenoids. This means the setting up of dental, ophthalmologic and minor surgical clinics. The local authorities are now ordered to provide for the medical inspection of persons under 18 attending secondary schools, pupil teacher centers, preparatory classes and junior technical schools. They may also make such arrangements as may be sanctioned by the board for attending to the health and physical conditions of the pupils attending secondary schools and other specified institutions. In the case of nursery schools, it is ordered that adequate arrangements must be made for attending to the health, nourishment and physical welfare of the children.

Justice to Animals

The Council of Justice to Animals has two objects: (1) to promote humane methods of slaughtering for food and (2) to provide for the painless killing, when necessary, of horses, dogs and other animals. In its thirteenth annual report, just issued, progress is announced in the cause of humane killing. The council lends instruments to any slaughterer willing to give them a trial and has persuaded 150 local authorities to make the use of such killers compulsory. It also presents lethal boxes and special pistols to pharmacists, police officials and others concerned in the destruction of unwanted or strayed cats and dogs. The council engages in active propaganda both at home and abroad. Demonstrations and missionary work in France, Spain, Belgium, Greece and other countries have been well received. France is rapidly adopting a killer called the "harmor" in preference to the mallet, by which an animal has often been struck ten blows. In Paris there is a demand for the two English captive bolt pistols, the demonstrations with which have been described by the French as "triumphant." In Rome, the annual slaughter of 150,000 animals has been handed over to a society of which Mr. Leonard Hawksley is honorary director, and under his inspector the captive bolt pistols are used, which means painless instead of extremely painful deaths for all these animals. The council commends this handing over of the slaughter of animals to a society for the protection of animals as a system which might be adopted in many English towns and so would do away with the horrors not only of killing but also of transit and handling in most slaughterhouses.

The Battle for Boric Acid

The ministry of health's regulation to prohibit the use of boric acid as a food preservative has given rise to much protest, which will make itself felt when the House of Commons meets again. Traders declare that the effect will be to restrict the importation of food and raise prices, particularly in the case of eggs, and that the risk of food poisoning will be increased, as venders will be tempted to conceal deterioration of food by cooking it in order that it may not be wasted. The equivalent of 1,000 million eggs in liquid form, preserved with boric acid, is imported from China annually. Canadian bacon and ham, colonial butter, margarin, cream, cakes and some cheese will also be affected. A great difficulty is that the cold storage facilities in this country are far short of those which will be required if boric acid is prohibited. A number of leading chemists and physicians have declared against the prohibition. Sir William Pope, professor of chemistry in Cambridge University, says that the nature of the evidence on which the ministry acted lacks an unimpeachable scientific basis. Dr. Robert Hutchison, a physician and authority on dietetics, states that if preservatives are abolished to the extent required there will be a great risk of food poisoning. Other protests have come from Prof. F. W. Tunicliff, physician to King's College Hospital; Dr. Panton, clinical pathologist to the London Hospital; Dr. J. C. Drummond, professor of biochemistry at the University of London, and Dr. J. Glaister of the University of Glasgow.

The Mode of Action of Oiling of Water in the Destruction of Mosquito Larvae and Pupae

The researches of Dr. Keilin of the Molteo Institute throw a new light on what happens when water is oiled for mosquito destruction. It has always been supposed that mosquito larvae and pupae are destroyed by the oil or paraffin layer preventing access of oxygen to the breathing tubes. But the process is not so simple. Dr. Keilin has discovered that certain cells of the breathing tubes produce fatty substances which prevent intrusion of water into the spiracles and tracheae of the larvae and pupae. He has shown that paraffin and other substances, such as chloroform and alcohol, destroy these fatty substances, and then water enters the spiracles and tracheae. It is this, and not the absence of oxygen, that produces suffocation.

Health of the Navy: Lowest Disease Death Rate on Record

A report on the health of the navy in 1922, just issued, shows a marked improvement in the general health as compared with the five-year period 1909-1913, and also as compared with 1921. The total force was 95,560, and the total number of cases of disease and injury was 53,979, which gives a ratio of 559 per thousand, a decrease of 81 as compared with the average for the five-year period. The total number of days' sickness on board and in hospital was 854,280, which represents an average loss of service of 8.84 days, a decrease of 0.65 as compared with the average. The Atlantic fleet shows the lowest sick rate, and the irregular list the highest. Deaths numbered 333, a ratio of 3.44 per thousand. There were 4,504 cases of influenza, 10,033 cases of venereal diseases, 6,900 of diseases of the respiratory system, 7,783 of diseases of the digestive system, and 7,077 of diseases of the areolar tissue and skin. Only two entries are returned of wounds and injuries in action. There were eleven cases of suicide. A table of the ratio per thousand of deaths in the service shows a steady decline from diseases alone from 12.1 in 1856, 14.7 in 1857, 22 in 1858, and 11 in 1859 to 1.97 in 1922, the lowest rate on record.

Filtrable Types of Tubercle Bacilli

Arloing, taking up again the question of filtrable types of tubercle bacilli, prepared filtrates of tuberculous lesions in man and of cultures of tubercle bacilli. The filtration was done with a Chamberland filter. As filter control, cultures of ordinary micro-organisms were mixed with the tuberculous products subjected to filtration. Each filtrate was afterward cultivated on various mediums to verify its sterility. After sterility was established, Arloing followed two methods: 1. He cultivated the filtrates in glycerinated peptone solution and in glycerinated bouillon. 2. He injected 2 c.c. of the filtrate into the peritoneum of a guinea-pig and subcutaneously into the thigh of another guinea-pig. He used successively filtrates of lesions from pulmonary inoculation of an infant, of subcutaneous tuberculoma taken from a child 2 years old, of a granulated lung, and of cerebrospinal fluid. He employed also recent cultures of tubercle bacilli on Petroff's culture medium.

All the animals were killed after one to two and a half months, which is too short a time. Arloing did not find a visceral lesion in any of the cases, but he observed swellings of the lumbar, mesenteric and tracheobronchial glands, and in these glands he found numerous tubercle bacilli. Arloing found no caseation, which caused him much surprise. All attempts to develop cultures with the filtrates proved of no avail.

Arloing's experiments, presented before the Société de biologie, seem to invalidate in part the researches of Vaudremer. Vaudremer stated that he obtained regularly cultures of acid-fast organisms from filtrates. However, Valtis also was unsuccessful in attempts to cultivate organisms from filtrates, though he succeeded regularly in tuberculizing guinea-pigs by injecting under their skin filtrates of tuberculous sputum passed through a Chamberland filter.

In three successive experiments, Valtis tuberculized three groups of guinea-pigs with filtrates of tuberculous sputum (*Annales de l'Institut Pasteur,* June, 1924). With filtrates of cultures he obtained similar results. He established this fact, now confirmed by Arloing: the existence of multiple glandular swellings in the inoculated guinea-pigs, many tubercule bacilli being found in the glands. He also found lesions in the viscera. He discovered many tubercle bacilli in pneumonic foci. In the lungs he found frankly caseous lesions with many tubercle bacilli. Arloing would doubtless have observed this condition if he had not killed his animals so soon. Valtis did not find caseous pulmonary lesions until after the lapse of three months.

Valtis brought to light the regular absence of an ulcer at the site of inoculation. It seems that the glands are the first stopping points of filtrable tubercle bacilli. Finally pulmonary lesions of two types appear: pneumonic or caseous, in which typical tubercle bacilli are found.

Recently, Durand and Charchansky pointed out, as did Valtis, that inoculation with filtrates may produce caseous lesions in the guinea-pig. They observed a large caseous gland near the spleen. Again, it is evident that Arloing would have secured similar results if he had not killed his animals so early. Valtis showed also that animals tuberculized with filtrates react very rapidly to tuberculin—almost as rapidly as animals inoculated with unfiltered tuberculous sputum.

Before Valtis, Fontés in 1910 had pointed out that granulations (so-called Much granulations) of tubercle bacilli pass through the Berkefeld filter. Having injected the filtrate into guinea-pigs, he found what he regarded as granulations in the spleens. Inoculating other guinea-pigs with the spleen, he found tuberculous glandular and pulmonary lesions. He had not, however, observed tuberculous lesions in the guinea-pigs into which he had injected the filtrate.

From these researches, the following facts are evolved:

The guinea-pig may be tuberculized with filtrates of tuberculous products. Animals thus tuberculized give positive skin reactions. No ulcer is observed at the site of inoculation, but gradually the glands begin to swell and finally caseous pulmonary lesions appear. All these facts have been brought to light by Valtis and have been confirmed by numerous authors. They are of real importance and should be taken account of in a number of problems bearing on tuberculosis.

The question of cultures from filtrates remains still undecided. Vaudremer and later Hauduroy allege that they obtained special types of acid-fast organisms, which they had been able to reproduce in a series. But, of late, the attempts to secure these cultures (Valtis, Arloing and others) have been negative, and it is a question whether the filaments described by Vaudremer and studied by him have any actual relation to the tubercle bacillus.

The question of filtrable types of tubercle bacilli seems to be becoming more clarified. Perhaps we may expect in the near future some interesting results which will modify our present conception of tuberculosis in man.

Mental Strain and Dementia Praecox

Dr. Deroitte has shown that there are more dementia praecox patients in Belgian than in English asylums. Examination of causes shows that this possibly is due to different methods of instruction and to errors in hygiene of the nervous system. Brain work must not exceed the resisting capacity of that organ. As a rule, pupils are compelled to devote some time to home study, and reforms in instruction have only resulted in overloading the study schedules and aggravating the evil. In an article in the *Scalpel,* Deroitte suggests that physicians always be associated with any commission appointed to revise the curriculum. The advice of physicians is needed in apportioning the mental and physical work that pupils of a given age can safely be required to do. Their presence would help suppress the medieval custom of assigning mental tasks as a punishment, which only irritate a pupil. Often, says Deroitte, a pupil who is punished for negligence is predisposed to mental disease and should receive additional care and attention. The author advocates complete revision along this line. Medical science, he says, should aid in elaboration of school curriculums, which so greatly affect the future of youth.

The Etiology of Trachoma

At the thirty-eighth congress of the Société française d'ophtalmologie, in Brussels, Morax of Paris and Cazalès of Béziers contributed papers on the etiology of trachoma. Morax thinks that children are infected, as a rule, by the mother, and offers this as an explanation of the trachoma which is endemic in Egypt, Morocco and Tunis, affecting at times from 90 to 95 per cent. of the inhabitants. Contagion by transmission is not a serious menace to adults. The principal objective in the crusade against trachoma must be prevention of transmission within the family.

Cazalès surveyed the pathogenic findings from two standpoints: first, conjunctival microbic infection by various organisms, one of which may predominate, and second, diathetic specificity. According to the latter view, trachomatous follicles may follow inflammatory modifications of the conjunctival epithelium and the underlying tissue.

The Law Pertaining to Public Charity

Administration of public charity in Belgium is being completely reorganized. Heretofore, an old law provided for two different organizations or societies: the bureau of charity and the commission on municipal shelters, the two being grouped under the name of commissions on public assistance. These commissions exist in nearly all communes. If the resources of certain communes are not sufficient, they are authorized to unite to form an intercommunal commission. In the most general sense, the objects of the commissions are to succor and provide hospital service for the poor. They decide in questions of indigence on allocation of benefits and on admissions to and dismissals from communal institutions. The commissions must organize medicopharmaceutic services for home care and create hospital services, maternity and isolation hospitals, either in their own institutions or in private establishments. They appoint and remunerate the physicians and functionaries of the various services, and, in general, all the workers of the bureaus of public assistance.

A new law, which is the outcome of discussions that began soon after the armistice was signed, went into effect in September and has introduced many reforms. The new law accords to the indigent free choice of physician, laboratory physician, pharmacist and midwife for home treatment. Thus, the two questions that interest the medical profession have been solved: 1. The organization of adequate medicosurgical equipment. This organization will be supervised by a medical inspector of hygiene, who will furnish an annual report to the minister of justice. 2. Owing to the free choice of physician, the commissions cannot employ physicians at ridiculously low salaries to treat the poor. Furthermore, the commissions will be urged to appoint medical councils to supervise medical expenditures and the care given patients. The medical councils will constitute connecting links between the physicians and the administration. The councils will authorize patients to be roentgenographed, operated on, examined by specialists, sent to a hospital, or provided with spectacles or orthopedic appliances. By obtaining the approval of the councils, medicines more satisfactory to practitioners as well as to patients may be employed. Every patient will be supplied with a book, in which will be recorded the principal administrative and medical facts pertaining to the patient. When occasion arises, the administration will give the record book to the physician. In the administrative record, which contains a blank space for every day in the year, the physician will enter a conventional mark every time he renders a service. Thus, the preparation of accounting and auditing will be easy. In the medical record, the physician will enter symptoms, diagnosis, and the treatment prescribed. A patient cannot be given conscientious care without this minimum of note taking. When, under former conditions, a physician to the poor received a mere pittance, he could not take time even for these entries. Now that the physician can count on fair remuneration for every service, he can practice without undue haste.

Aside from the medical organization that we have thus outlined, the new legislation reaches out into social fields. Article 1 develops the idea that the commissions must not only relieve but also prevent poverty and misery. The commissions may grant subsidies or make reimbursable advances to provident societies, demanding, as far as possible, a personal contribution from those affiliated on payment of their annual dues. With the same purpose in view, the commissions may build or buy reasonably priced houses, or participate in the work of societies pursuing such aims as the creation and development of workmen's gardens. Indeed, the administrations are urged to enter into the present-day movement, which emphasizes insurance and provision for the future.

Tar Cancer

In general, the experimental and pathologic cases of occupational cancer are regarded as of purely local origin. Maisin and Masse before the Société belge de biologie seem to oppose this view. These authors have pointed out that, in addition to its local irritant action, tar exerts a general toxic action on the mouse, so that the organism develops cancer more readily than a normal organism. In view of the theories recently advanced that cancer is a general disease, these findings are valuable.

Welfare Treatment of Venereal Patients

The transactions of the German Society for Combating Venereal Diseases, which was held in Dresden in September, had to do less with medical than with social and hygienic welfare treatment among venereal patients. The opening paper on the subject "Cooperation in the Welfare Treatment of Venereal Patients and in the Institution of Prophylactic Measures" was presented by Irmgard Jäger, who is connected with the welfare department of Mecklenburg-Schwerin. The gist of her argument follows: In former years prostitution was the main cause for the spread of venereal diseases, and to curb those diseases necessitated an energetic campaign against the evils of prostitution. Today, in addition to prostitution, welfare workers must extend their field and consider the increase of extramarital sexual intercourse. Police provisions and medical measures are not adequate. Mild and tactful expedients are needed to aid those menaced; more particularly, the juvenile element of the population. The so-called caritative societies pursue different aims, and their members are not always willing to operate in the difficult field described. The sole presentation of purely ethical teachings in routine fashion will not accomplish the purpose sought. Those who are menaced must be given an opportunity to improve their social and economic position. Welfare workers must have received thorough training for their work, and must have good judgment and tact. Their moral and ethical qualities must be unassailable. Cooperation with physicians and welfare organizations, and with police stations and health insurance societies is essential. Such cooperation can be effected if all parties concerned will only show the proper good will, as in Mecklenburg-Schwerin, where there is limited compulsory reporting of venereal patients. Physicians report venereal patients to the welfare centers if they appear likely to withdraw from treatment or if they have failed to reappear during a physician's office hours, while taking treatment. No documentary correspondence is carried on, for reasons of discretion. The welfare workers get in touch with the persons concerned in an inobtrusive way, and seek to influence them by a personal interview. If the welfare workers are able to give them effective aid, they usually can influence them ethically and morally. In this way, many young girls are saved who would otherwise degenerate. Many venereal patients are unable in their surroundings to carry out the treatment that the physician has prescribed. Bad housing conditions and certain occupations (maids, employees) make this difficult. If the nature of the disease becomes known, the patient runs a risk of losing her position and of being damaged socially. On the other hand, if female venereal patients are brought much in contact with other persons, especially children, it is an exceedingly serious matter. The physician is unable, under such circumstances, to render aid. The welfare worker, on the other hand, finds here an opportunity to do some of her best work. She can put her protégées in touch with all welfare agencies: the caritative societies, the federal insurance bureau, the consultation centers and the health insurance societies. Methods of cooperation have been worked out in many cities with excellent results.

Prof. Herwart Fischer of Wurzburg spoke on "The Necessity of Thorough Medical Treatment of Venereal Patients in Our Jails and Prisons." During his five years as prison physician in Breslau, a large percentage of the prisoners had venereal disease; 17 per cent. were suffering from syphilis. This finding is in apparent conflict with the number of syphilitic patients in other penal institutions. The difference is due to the fact that heretofore only those prisoners had been designated as syphilitic who presented marked symptoms. The routine Wassermann test, which was applied in several penal institutions at the instance of Professor Fischer, revealed that in some prisons the proportion of syphilitics was 20 per cent. Fischer figures that there are about 125,000 syphilitic patients in German penal institutions every year, of whom only 20 per cent. receive treatment. Around 100,000 received inadequate treatment or none at all. Most prisoners are of inferior moral character and are chiefly unsocial, irresponsible persons, who represent a great source of infection. Fischer favors the most effective modern treatment for prisoners with venereal disease for which their stay in prison presents a favorable opportunity. If needed, treatment should be assured after their dismissal until they are cured. In some cities, a corps of specialists and trained personnel give consistent treatment to all venereal prisoners, and the results have been good. The main difficulty in the way of carrying this out universally is the great expense that it entails. Fischer thinks that the state should not bear all the expense but that demands should be made on the provincial insurance bureaus, the health insurance societies, and, in some cases, the prisoners themselves.

The second speaker on this subject, Prof. Dr. Galewsky, reported on his investigations and the measures adopted in the Saxon penal institutions. In cooperation with the state officials, he worked out the plans introducing all possible measures that govern treatment of venereal prisoners. In Dresden the conditions are especially favorable; the penal institutions have excellent rooms for treatment and well trained specialists. The ministry of justice and the state officials have done what they could to further the undertaking. Every prisoner must be treated; the nature of the treatment is left to the physicians appointed by the state. In addition to treatment, it is well to give the prisoners needed instruction by lantern slides and appropriate leaflets.

Marriages

James Mortimer Pierce, Ann Arbor, Mich., to Miss Doris Alice Will of Lockport, N. Y., August 18.

Gordon Wesley Batman, Indianapolis, to Miss Mildred Hauss of Sellersburg, Ind., August 12.

Lloyd O. Peckenschneider to Miss Helen Marie Fellner, both of Davenport, Iowa, June 30.

James G. Sandidge, Mulberry, Mo., to Miss Maude Curran of Burgess, at Neosho, August 6.

Stuart Broadwell, Jr., to Miss Mary Temple Smith, both of Springfield, Ill., in September.

Karl Monroe Koons, Indianapolis, to Miss Catherine Miller of Warren, Ohio, August 8.

Lyman H. Hoyt, Iowa City, to Miss Helen Sawyer of Greenfield, Iowa, June 10.

Capl Edgar Sampson to Miss Eileen Reardon, both of Creston, Iowa, June 10.

Neil E. Funk, La Porte, Ind., to Miss F. Lois Miller of Chicago, June 25.

Dexter A. Buck to Miss Grace Powell, both of La Porte, Ind., June 31.

Deaths

Louis Starr, Dinard, France; University of Pennsylvania School of Medicine, Philadelphia, 1871; instructor of physiology and therapeutics, 1874-1877; lecturer on diseases of children, 1880-1884, and clinical professor of diseases of children, 1884-1890, at his alma mater; at one time on the staffs of the Episcopal, Children's, University and Maternity hospitals and the Southern Home for Destitute Children, Philadelphia; formerly assistant editor of Pepper's System of Medicine, American editor of Goodhart's Diseases of Children, author of a textbook on diseases of children and other works; aged 76; died, September 12.

Walter Porter Manton ⊕ Pasadena, Calif.; Medical School of Harvard University, Boston, 1881; member of the Michigan State Medical Society; the American Gynecological Society, and the Royal Medical Society of London; emeritus professor of obstetrics, Detroit College of Medicine and Surgery; at one time on the staffs of the Harper, Herman Keifer and Women's hospitals and St. Joseph's Retreat, Detroit; author of medical books and a contributor to textbooks and medical journals; aged 68; died, September 24, following a long illness.

David Ernest Hoag ⊕ Pueblo, Colo.; Kansas City (Mo.) Hahnemann Medical College, 1905; University of Maryland School of Medicine, Baltimore, 1908; member and at one time president of the Associated Anesthetists of the United States and Canada; secretary of the Pueblo County Medical Society; aged 43; died, September 18, of septic appendix.

Samuel Boyce Pole ⊕ Washington, D. C.; George Washington University Medical School, 1909; clinical instructor of laryngology and otology at his alma mater; on the staffs of the Episcopal Eye, Ear and Throat Hospital and the George Washington University Hospital, where he died, September 24, of septicemia, aged 39.

Frederick William Lux ⊕ San Francisco; Medical School of Harvard University, Boston, 1885; formerly professor of clinical medicine, College of Physicians and Surgeons of San Francisco; at one time on the staff of the San Francisco Hospital; aged 64; died, September 20, at St. Francis Hospital, of chronic myocarditis.

Albert Miles Taylor ⊕ San Francisco; Missouri Medical College, St. Louis, 1883; formerly professor of gynecology and abdominal surgery, College of Physicians and Surgeons; aged 66; died, September 18, at St. Francis Hospital, of chronic myocarditis and diabetes mellitus.

G. E. Whitlock, Columbus, Ill.; Jefferson Medical College of Philadelphia, 1876; member of the Illinois State Medical Society; past president of the Adams County Medical Society; aged 74; died, September 19, at the Blessing Hospital, Quincy, of chronic nephritis.

Frederick William Kappelman, Milwaukee; Northwestern University Medical School, Chicago, 1912; member of the State Medical Society of Wisconsin; on the staffs of the Deaconess and Emergency hospitals; aged 50; died, September 26.

Zachary Talmage Penhorwood, Greenville, Ohio; Ohio State University College of Medicine, Columbus, 1915; member of the Ohio State Medical Association; aged 33; died, September 13, at Philadelphia, following an appendectomy.

Richard Fyfe, Chicago; Medical Department University of Illinois, Chicago, 1893; member of the Illinois State Medical Society; formerly on the staff of the Home for Crippled Children; aged 55; died, August 3, of pulmonary tuberculosis.

Jacob J. Russler, St. Louis; St. Louis University School of Medicine, 1903; member of the Missouri State Medical Association; formerly on the staff of St. John's Hospital; aged 50; died, September 19, of cerebral hemorrhage.

John Ladd Burnham, Portland, Conn.; Yale University School of Medicine, New Haven, 1899; member of the Connecticut State Medical Society; aged 54; died recently, at Antofagasta, Chile.

Neill Davies Johnson, Fort Myers, Fla.; Chicago Homeopathic Medical College, 1903; formerly a practitioner in Kansas and Missouri; aged 72; died, September 19, following a long illness.

Alexander Marshall Purdy, Mystic, Conn.; University of Vermont College of Medicine, Burlington, 1884; member of the Connecticut State Medical Society; aged 63; died, September 23.

Albert Todd Post, New York; Jefferson Medical College of Philadelphia, 1896; assistant medical director of the Equitable Life Assurance Society; aged 52; died, September 21.

John Dudley Cooke, Shortsville, N. Y.; College of Physicians and Surgeons, Buffalo, 1882; member of the Medical Society of the State of New York; aged 70; died, September 17.

Kenelm Leggett, Hobgood, N. C.; Kentucky School of Medicine, Louisville, 1884; member of the Medical Society of the State of North Carolina; aged 73; died, September 20.

Thomas Moffett Sherman, Kennard, Texas; Kentucky School of Medicine, Louisville, 1883; member of the State Medical Association of Texas; aged 74; died, September 14.

William T. Sewell, Baxter, Tenn.; University of Tennessee College of Medicine, Memphis, 1894; aged 61; died, September 11, at a hospital in Nashville, following a long illness.

Howard F. King, Windsor, Conn.; Albany (N. Y.) Medical College, 1899; member of the Connecticut state Medical Society; aged 53; died, September 19, of angina pectoris.

Thomas Chowning ⊕ Hannibal, Mo.; Missouri Medical College, St. Louis, 1875; formerly on the staff of the Levering Hospital; aged 73; died, September 16, of pneumonia.

Felix Constantine Harman, Ottoville, Ohio; Starling Medical College, Columbus, 1905; member of the Ohio State Medical Association; aged 44; died, September 15.

James Moore Wilson, Douglas, Wyo.; Jefferson Medical College of Philadelphia, 1878; aged 71; died, September 13, at the Douglas Hospital, of cerebral hemorrhage.

Hermann F. Kudlich, New York; University of Vienna, Austria, 1869; member of the Medical Society of the State of New York; aged 81; died, September 26.

Alonzo C. Taylor, Baldwinsville, N. Y.; Philadelphia University of Medicine and Surgery, 1865; Civil War veteran; aged 83; died, September 22, of senility.

Luther Lee Johnson ⊕ East Florence, Ala.; University of Wooster Medical Department, Cleveland, 1880; aged 68; died, September 15, of heart disease.

John Dowell Combest, Loretto, Ky.; Kentucky University Medical Department, Louisville, 1905; aged 52; died, September 18, at a hospital in Lebanon.

William Sommerville Woodworth, Kentville, Nova Scotia, Canada; Medical School of Harvard University, Boston, 1873; aged 77; died, July 22.

Arthur Monroe Calvert, Akron, Ohio; Medical College of Indiana, Indianapolis, 1903; aged 49; died, September 17, of intestinal obstruction.

Frank Wheeler, Plainfield, Vt.; Hahnemann Medical College and Hospital, Chicago, 1882; aged 73; died, September 14, of heart disease.

Norman William Anderson, Lumsden, Sask.; Queen's University Faculty of Medicine, Kingston, Ont., 1898; aged 55; died, August 28.

James Miner, Winchester, Ill.; Jefferson Medical College of Philadelphia, 1861; Civil War veteran; aged 90; died, September 18.

Elija F. Mulkey, Commerce, Texas; Vanderbilt University Medical Department, Nashville, Tenn., 1881; aged 83; died, September 19.

Henry F. Webb, North Little Rock, Ark. (licensed, Arkansas, 1903); aged 59; died, September 15, at a hospital in Little Rock.

Melvin Wilson Hill, Mount Vernon, Iowa; College of Physicians and Surgeons, Keokuk, 1881; aged 73; died, September 11.

William A. Hutchins, Orangeville, Ill.; Rush Medical College, Chicago, 1885; aged 65; died, September 22.

Otto Moritz Schall, St. Louis; Barnes Medical College, St. Louis, 1904; died, September 11.

The Propaganda for Reform

In This Department Appear Reports of The Journal's Bureau of Investigation, of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

ADROPSEDEMA

A Recrudescence of Shotgun Therapy

"Adropsedema," sold by the Van Seaton Chemical Company of Fort Worth, Texas, and Chicago, Ill., is a "dropsy cure" of the Anasarcin type. Recently the medical profession has received circulars exploiting its merits.

Twenty years ago "shotgun" proprietaries hindered therapeutic advance and rational drug therapy. The multiplicity of their ingredients made scientific judgment of their action impossible. The physician, attracted by advertisements in almost every medical journal and the panegyrics of detail men, sometimes put aside the instruction he had received in medical school and followed the extensive treatises and "hints for the busy doctor" which the beneficent proprietary fraternity lavished on him. Happily, the day of the complex mixture is practically over. The convincing reports of the Council on Pharmacy and Chemistry on such widely exploited preparations; the enlightening analyses of the A. M. A. Chemical Laboratory, showing that the declarations of composition by manufacturers were not to be taken for gospel truth; the exposures of the Bureau of Investigation (then the Propaganda Department), giving an insight into the personnel of the firms which marketed these mixtures and their methods of obtaining so-called therapeutic evidence—all these have brought home to the medical profession the uncertainty and folly of prescribing a heterogeneous mixture of drugs.

The effect which the educational activities of the American Medical Association has had on the "shotgun proprietary" can best be realized (1) by examining the advertising pages of those self-styled medical journals that still lend their support to the nostrum business and (2) by studying the advertising material sent to the physician through the mails. The complex mixtures which were extensively exploited twenty years ago are, as a rule, no longer the subject of blatant advertising. If they are advertised at all it is only by an occasional half-hearted announcement or circular. More important still, the pharmaceutical firms which formerly pushed imitations of all the widely advertised nostrums are no longer featuring this part of their business and are slowly but surely removing many of these formulas from their catalogues.

Adropsedema comes in the form of tablets—one hundred in a three-sided, prettily decorated tin box which will be sent for one dollar and twenty-five cents. According to this box, Adropsedema is "a scientific remedy for the relief of general dropsical conditions." For "dropsical conditions," *one or two tablets every four hours are to be taken, followed* the next morning by salts until desired results are obtained. As a 'heart tonic," one or two tablets are to be taken every four hours. While the style of the package and the directions which appear on it will no doubt lead to its use by the public, the promoters of this nostrum anticipate criticism by placing on the box the statement that this preparation should always be used under the direction of a physician.

In the marketing of complex mixtures, it is the custom to make much of the complexity: the asserted virtues of each ingredient are vaunted separately and then all are combined *to make a miraculous whole. Of course, its very complexity* makes it impossible to use such a preparation intelligently; but the promoter hopes to induce the thoughtless and uncritical to make a trial of the blunderbuss.

In line with precedent, the promotors of "Adropsedema" ask physicians to "study the formula." A formula which is given in a circular reads: strophanthin 1-240 gr.; spartein sulphate 1-64 gr.; "apocynin" 1-4 gr.; "ext. urginea scillae" 1-5 gr.; "gelsemin" 1-8 gr.; "extract sambucus" 1 gr.; ferrous carbonate 1-2 gr. Elsewhere the "formula" includes "cactus grandifolium, 4 gtt.," "gelsemium" instead of "gelsemin" and *"reduced iron" instead of ferrous carbonate. The "cactus* grandifolium, 4 gtt." probably refers to some liquid preparation of cactus grandiflorus.

So that the physician may the better "study the formula," the Van Seaton Chemical Company graciously supplies him with a statement of the virtues of each ingredient, except the "cactus grandifolium." The physician who cares to continue the study of this conglomeration beyond the point furnished by the manufacturer will appreciate the following excerpts from the Epitome of the U. S. Pharmacopeia and National Formulary published by the American Medical Association:

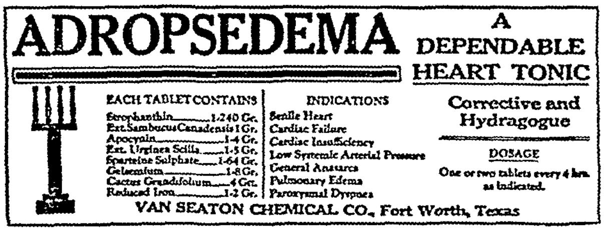
APOCYNUM (Canadian Hemp), N. F. "Action and uses: Cardiac tonic of digitalis group: unreliable as to rate of absorption." [The "formula" refers to "Apocynin," which is a name that has been applied to extractive preparations of indefinite composition of apocynum.]

SAMBUCUS (Elder Flowers), N. F. "Action and uses: Obsolete and worthless remedy in dropsy. Large doses are said to act like a hydragogue cathartic."

GELSEMIUM (Yellow Jasmine Root), U. S. P. "Action and uses: Used in migraine and neuralgia, and in the treatment of ovarian, rheumatic and uterine pain. Efficiency uncertain. Untoward symptoms sometimes result from comparatively small doses."

SPARTEIN SULPHATE, U. S. P. "Action and uses: Has been widely exploited as a diuretic, but on insufficient evidence. Is of little use and is now less frequently employed than formerly. Large doses slow and weaken the heart."

CACTUS GRANDIFLORUS (Night Blooming Cereus), N. F. "Action and uses: Used in neurotic heart disturbances; results probably imaginary. Drug apparently inactive."



ADROPSEDEMA
A DEPENDABLE HEART TONIC

EACH TABLET CONTAINS
Strophanthin 1-240 Gr.
Ext. Sambucus Canadensis 1 Gr.
Apocynin 1-4 Gr.
Ext. Urginea Scilla 1-5 Gr.
Sparteine Sulphate 1-64 Gr.
Gelsemium 1-8 Gr.
Cactus Grandifolium 4 Gr.
Reduced Iron 1-2 Gr.

INDICATIONS
Senile Heart
Cardiac Failure
Cardiac Insufficiency
Low Systemic Arterial Pressure
General Anasarca
Pulmonary Edema
Paroxysmal Dyspnea

Corrective and Hydragogue

DOSAGE
One or two tablets every 4 hrs. as indicated.

VAN SEATON CHEMICAL CO., Fort Worth, Texas

Greatly reduced facsimile of one of the advertisements used in exploiting "Adropsedema."

The quotations just given represented the estimate of the drugs in question of the Council on Pharmacy and Chemistry and appeared in "The Epitome," which was issued in 1916. Since then our knowledge of the real value of drugs such as apocynum, elder flowers and spartein has been crystallized. Of all the drugs named in the "adropsedema" formula, only three (strophantin, squill and ferrous carbonate) are to be found in the recently issued Pharmacopeia of the United States!

In the advertising it is claimed:

> "Adropsedema is used successfully in chronic myocardial insufficiency, Bright's disease, valvular lesions, endocarditis, acute myocarditis, functional diseases of the heart, or wherever the normal equilibrium between the arterial and venous systems is disturbed."

The thoughtless and ill-considered use of this preparation is suggested by statements such as:

> "It has demonstrated its adaptability in many forms of dropsy."
>
> " . . . absolutely devoid of the manifestations of gastric disorders and cumulative action so frequently attending the administration of the more powerful cardiac remedies separately."
>
> "Adropsedema does the work; what more do you want? When in suspense prescribe Adropsedema."
>
> "When in doubt, prescribe Adropsedema. Adropsedema for 'dropsies'; first, last and all the time."

In one of the circulars issued by the Van Seaton Chemical Company, Adropsedema is referred to as "a preparation with a conscience." Were inanimate objects possessed of a conscience, Adropsedema would no doubt feel thoroughly ashamed of itself. This also is applicable to the Van Seaton Chemical Company, which though composed of animates, may be charitably thought of as an inanimate entity. It is difficult to imagine how a member of a learned profession could satisfy his conscience were he to prescribe the unscientific mixture foisted on him under the name of "Adropsedema."

Correspondence

AMERICAN BIRTH CONTROL LEAGUE

To the Editor:—In THE JOURNAL, September 19, p. 908, a resolution on birth control is reported from a recent meeting of the Rock Island County Medical Society condemning affiliation by any member with the American Birth Control League and labeling such affiliation unethical and unprofessional conduct. This action impels me to state briefly the experiences of the Committee on Maternal Health with the officials of this league.

When the committee's review appeared in the *American Journal of Obstetrics and Gynecology,* Mrs. Sanger sent their medical director to ask how the criticisms of the league contained in that report could be met. He was referred to the Public Health Committee of the Academy of Medicine and submitted to it a proposition from the league to carry out any alterations in method that would make its practice professionally ethical. It developed that 7,000 physicians had applied to the league for information on contraception and that nearly 1,000 letters a week were received from the laity asking for counsel. A committee was appointed to investigate. It reported as follows:

> In view of the fact that many existing hospital clinics in the city of New York are reluctant to carry on such study; and those which have entered on it are not generally known to have undertaken it, there is a provisional need of a special clinic; that, although lawfully practicing physicians are permitted under the statute to give contraceptive advice "for the cure or prevention of disease," they do not usually take advantage of this provision of the law (Section 1145 of the penal law): Therefore, it is the opinion of your subcommittee that there is, for the time being, a need in New York City for a clinic under nonhospital auspices for the purpose described above, provided that this special clinic obtains legal sanction from the state board of charities, and that it has an adequate personnel and equipment for diagnosis and research, and an advisory board of gynecologists and obstetricians of recognized authority to guide its policies and work, and inspect it regularly.

Later, Mrs. Sanger appeared before the state board of charities and a plan was submitted whereby such a clinic should be under responsible and representative medical control. This plan is being actively pushed.

Further investigation by the Committee on Maternal Health developed the fact that the American Birth Control League has strongly opposed the Voluntary Parenthood League in the latter's contention that proper action was the removal by Congress of all restrictions on sending contraceptive information through the mails. In the contest for the Cummings-Vaile bill which proposed to make this alteration in the federal postal law, the Sanger group seems to have taken no part. On the contrary, this league's literature shows that it is working for the "doctors only" amendment. In conference with our committee's legal advisers, the American Birth Control League agreed to push such amendments as the one passed in May by the American Gynecological Society and the second endorsed at the last meeting of the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association. The Gynecological Society vote was a close one because of the inclusion of the word "reprints." There was no opposition raised at Atlantic City.

1. Standard medical and scientific journals and reprints therefrom and standard medical works which contain information with reference to the preventing of conception are not nonmailable under this section (federal postal law).
2. *Resolved,* That we hereby recommend the alteration of existing laws wherever necessary so that physicians may legally give contraceptive information to their patients in the regular course of practice.

The Committee on Maternal Health has secured, in seven gynecologic clinics in Greater New York, a study of indications for and methods and results of, birth regulation. These are, from north to south, Lebanon Hospital, the Woman's Hospital, Mount Sinai Hospital, Sloane Hospital, New York

Infirmary, Brooklyn Hospital and Long Island College Hospital. It also is investigating sterilization and sterility. Under complete medical control, with the endorsement of its plans by the New York Obstetrical Society, the Academy of Medicine and the American Gynecological Society, this committee is furthering and partly financing researches on long range methods of control of ovulation and spermatogenesis as well as the ordinary mechanical handicap methods. Our survey in France demonstrates that its medical profession cannot show what means have curtailed the birth rate; that Holland has not and has never had birth control clinics in any sense in which we use the word clinic, and has not gathered information on the subject, and that the several English clinics, lacking control by any gynecologist or obstetrician of standing, show no follow-up of value. We are, therefore, seeking for trustworthy information from every source, and would prize any returns from clinical studies on "therapeutic contraception" from Rock Island County, or a list of their institutions giving instruction to patients whose life or health would be jeopardized by pregnancy.

Robert L. Dickinson, M.D., New York.
Secretary, Committee on Maternal Health.

"ANACIN"

To the Editor:—In the article on this subject, page 1079, October 3, it is stated that Dr. F. W. Wittich developed a formula for a "patent medicine" and allowed it to be put on the market for indiscriminate sale to, and the uncritical use by, the public.

The undersigned is the president of the Heidbrink Company of Minneapolis, which is the owner of the Trade Mark "Anacin." This trade mark was acquired from a pharmacist in Minneapolis who claimed that the formula had been suggested to him by a number of prescriptions compounded by him for Dr. Wittich. This pharmacist had the name "Anacin" trade marked and he originated the name.

For a short time the sales manager printed on direction sheets accompanying each package "From a prescription of Dr. Wittich," with the idea of conforming to a rather extensive practice at that time of so accounting for proprietary medicines. This was done without my notice and without the knowledge or consent of Dr. Wittich.

When the matter was called to the attention of Dr. Wittich, he protested against the unwarranted use of his name, and the practice was stopped immediately and his name has never been so used since. At this time the inference that Dr. Wittich was connected with the manufacture and sale of Anacin was thoroughly investigated by the administrative board of the medical department of the University of Minnesota, which board completely exonerated him from any interest in or connection with the vending of "Anacin" or its use commercially.

At no time has Dr. Wittich had any interest in or connection with the manufacture and sale of "Anacin." He has never been a stockholder in our company and has never received a cent, either directly or indirectly, for the formula or sale of "Anacin."

In November, 1920, this company designed to submit the formula of "Anacin" to the Council on Pharmacy and Chemistry of the American Medical Association for its approval or rejection, and later for that purpose requested Dr. Wittich to give a statement of the therapeutic action of its ingredients. Such statement was given containing reference to authorities standard at the time, but no reference was made to the word "Anacin."

So far as I know, no use was ever made of this statement other than that about Aug. 12, 1925, our company received a letter from a physician in Michigan stating that a patient of his had been using "Anacin" and, because of its therapeutic action, he was anxious to learn more about it and desired to know the ingredients contained in the tablet. I sent to this physician a copy of Dr. Wittich's statement referred to above, as the best information available, as this company had no medical director connected with it. This was done without Dr. Wittich's knowledge or consent, and I had no idea of conveying the impression that Dr. Wittich was connected with our company.

My unfortunate statement in this letter that the "Anacin" formula was worked out by Dr. Wittich and his associates should be corrected. The origin of this formula is as stated above.

The only other communication we ever had from Dr. Wittich with reference to "Anacin" was the latter part of 1922, when he advised us to change the formula.

All advertising such as illustrated in your article appeared long after any communication with Dr. Wittich, and he is in no manner responsible concerning it.

J. A. Heidbrink, D.D.S., Minneapolis.

USE OF GENTIAN VIOLET IN THRUSH

To the Editor:—Through a regrettable inadvertence in preparing our clinical note on the gentian violet treatment of thrush (The Journal, September 19, p. 900) we failed to mention the work of Churchman, whose priority in the experimental and clinical study of gentian violet is, of course, well known. We have found, since submitting our manuscript, that Churchman in 1921 (Further Studies of the Behavior of Bacteria Toward Gentian Violet, *J. Exper. Med.* **33**:569 [May] 1921) reported that "in a plain agar plate . . . strokes of stained gram-negative organisms, for example *Bacillus subtilis* and *Oidium albicans*, will not grow at all" and showed photographs illustrating the point. While our own study was made in ignorance of these observations, we take pleasure in acknowledging them now. It is, of course, gratifying to us to find experimental support for our clinical impressions.

Harold K. Faber, M.D.
Lloyd B. Dickey, M.D., San Francisco.

DETERMINATION OF B. COLI INFECTION

To the Editor:—During a bacteriologic examination of the water coming from a certain reservoir, organisms were found belonging to the *B. coli* group, producing fermentation, acid and indol. In a search for the source of the contamination, a micro-organism possessing the same qualities in all respects was found in the colon of frogs infesting the reservoir. The following questions present themselves: (*a*) Are any methods known to differentiate between the human *B. coli* and that of the frog? (*b*) What is known of the pathogenicity of this micro-organism, and does its presence in water (all human sources of contamination having been excluded) make the water unfit for household use?

Peter Mjedloff, M.D., Puunene, Maui, H. I.

Answer.—Much work has been done on the perplexing question of the differentiation of the different members of the colon-aerogenes group of bacteria. It was supposed for a time by some that the aerogenes type of lactose fermenters was of less significance than the colon type in sanitary water examination and could be clearly distinguished from the latter. The methyl red positive and Voges-Proskauer negative cultures were commonly assumed to be of fecal origin and hence indicative of sewage contamination. Recent investigations, however, have shown that not all of the methyl red positive colon group are of fecal origin, since they are found in some abundance in certain uncontaminated soils. Less weight is therefore attached to these tests than formerly. The utilization of citrate proposed as a differential test by Koser (*J. Bacteriol.* 9:59 [Jan.] 1924) may prove a valuable differential test and may enable us to assign members of the colon-aerogenes group found in nature to a fecal or nonfecal source. At present the attempt to determine certainly whether a given culture of the colon-aerogenes group found in water is of human fecal origin meets almost insuperable difficulties. It need hardly be said that the interpretation of the presence of these organisms is based on the greater or less probability of their association with pathogenic intestinal forms. There is no reason to believe that the various members of this group as found in natural water are themselves able to produce infection when the water is used for drinking.

NEUROSINE

To the Editor:—I find that some physicians still use the discredited nostrum "Neurosine." Could you publish prominently the formula of the contents of each fluidounce as given by the manufacturers? That formula does not appear in the firm's primary advertising, and the physician who might be led by the insistent emphasis on its harmlessness to prescribe Neurosine could not realize the amount of bromid he would be prescribing. Oliver T. Osborne, M.D., New Haven, Conn.

Answer.—The Council on Pharmacy and Chemistry in a Report (The Journal, Jan. 9, 1915, p. 165) found Neurosine (Dios Chemical Company, St. Louis) to be a "shot gun" nostrum which violates practically every principle of modern therapeutics. This report was later reviewed at length (The Journal, April 27, 1918, p. 1251) with further confirmation of the Council's conclusions. The manufacturers still claim the formula then published, namely:

Each fluid ounce represents:
40 grains C. P. Potassium Bromide
40 grains C. P. Ammonium Bromide
40 grains C. P. Sodium Bromide
1 grain C. P. Zinc Bromide
32 grains Extract Lupuli
.60 grains Extract Cannabis Indica
.075 grains Extract Belladonna
.075 grains Extract Henbane
40 minims Extract Cascara Sagrada
.060 grains Oil Bitter Almonds
5% Alcohol and Aromatic Bitters

Neurosine therefore contains 121 grains of bromid in each fluidounce. When it is considered that the manufacturers recommend "the average dose of Neurosine" as "one dessert spoonful three or four times per diem," the fact appears that the thoughtless prescriber of this nostrum would be giving from approximately 90 to 120 grains (6 to 8 gm.) or more of bromids daily.

Useful Drugs, 1925, states under dosage for potassium bromid, "1 Gm. or 15 grains . . . after meals and at bed time. The dose may be increased to 5 Gm. if a powerful action is indicated." The danger of administering such a preparation as Neurosine without knowing its bromid content is, therefore, readily apparent.

SCOPOLAMIN IN OBSTETRICS

To the Editor:—A friendly controversy has occurred in our society as to the wisdom of ever using scopolamin (hyoscin) hydrobromid in obstetric cases. Will you give us your opinion as to the smallest dose that has ever proved fatal, and as to the dose that might ordinarily be expected to be fatal to an adult in good health? Kindly omit name.

J. A. R., New Mexico

Answer.—The lethal dose of scopolamin has not been determined for man (Witthaus and Becker). The smallest fatal dose of scopolamin hydrobromid recorded in the literature is 1/100 grain (0.6 mg.). This was given with one-eighth grain (8 mg.) of morphin, and the patient died two hours later (Ely).

Since there is a great difference in the ability of persons to recover from poisoning due to the atropin series, statements regarding "the dose that might ordinarily be expected to be fatal" may be misleading. In contrast to Ely's case are the reports of individuals who received as much as one-tenth grain (6 mg., Zimmerman), one-seventh grain (9 mg., Korn) and one-fifth grain (13 mg., Stolle), all of whom recovered.

Regarding the use of scopolamin in obstetric cases, there need be little fear of maternal mortality. De Lee says of scopolamin, "While the life dangers to the mother can be eliminated, the patient must be willing to pay the price of possible lacerations." Williams says, "It [scopolamin] has no effect on the maternal mortality." Haultain gave one patient in labor fifty-three doses of scopolamin, the first dose of which was 1/150 grain (0.4 mg.) and the fifty-two subsequent ones were each 1/450 grain (0.1 mg.). In a series of 1,604 deliveries, Van Hoosen gave twenty patients more than fifteen doses of scopolamin hydrobromid, each dose being 1/100 grain (0.6 mg.). One of these patients received thirty-one doses.

While a moderate number of fatal cases of scopolamin poisoning have been reported in the literature, careful examination of these reports reveals the fact that other drugs and anesthetics were used with the scopolamin and that death in some instances at least was not due to the scopolamin. Nicholson, who gave a kitten 3 grains (0.2 gm.) and a small cur 5 grains (0.3 gm.) of scopolamin without a fatal result, showed experimentally that the toxic doses of scopolamin and morphin correspond very closely to that of morphin alone for the animals used.

PROSTATITIS

To the Editor:—I am greatly interested in a case of prostatitis. A man, age 39, had gonorrhea about seventeen years ago, at which time he had an abscess which required catheterization for the urine for several days when the abscess broke into the urethra. Three months before I saw him he was troubled with distress before and during bowel movement, and his condition was diagnosed as a grade 4 prostatitis, seven infected teeth, and a grade 2 infection of the tonsils. Otherwise the examination was negative. He was advised to take massages of the prostate, which he has been taking for about three months, with considerable improvement in the symptoms. There is not any physician in any of our neighboring towns or cities that has had any experience with massaging in this condition. He was advised to have gentle massages. He wonders whether massages given by an inexperienced man might predispose to carcinoma. Have you any statistics to show the frequency of carcinoma following prostatitis? Is it a predisposing factor? Why was gentle massage recommended? Is there anything in diathermy or quartz lamp therapy or in the electrotherapeutic field that has shown good results in these cases? Could the infection have been in his prostate all these years since the gonorrhea? Would you advise exercise for him? If you should answer this in The Journal, please omit my name. M.D., Wisconsin.

Answer.—There is no tangible evidence that prostatitis is in any causative connection with cancer of this gland.

Brusque massage of the prostate may lead to injury to the glandular tissue and is apt to produce nervous symptoms. Massage of the prostate is safely done by using a club-shaped metallic instrument devised for this purpose. This appliance may be purchased at any medical supply house.

It is highly probable that the condition referred to dates back to the gonorrheal infection.

Diathermy furnishes excellent results in cases of chronic prostatitis. It is applied by placing a large indifferent electrode on the abdomen and a prostatic electrode in the rectum. The milliamperage is raised until the patient feels decided warmth but not heat in the rectum, and is maintained at this level during the entire treatment, which should last about twenty minutes. These treatments are repeated every third day until the patient is free from all symptoms.

There is no objection to moderate exercise except bicycle or horseback riding.

BENEDICT TEST FOR SUGAR

To the Editor:—In The Journal, July 11, in reply to an inquiry of Dr. George S. Silliman regarding Benedict's quantitative test for sugar, you end your reply by stating that "If this white precipitate of cuprous thiocyanate is not obtained, provided glucose is present there is probably something faulty with the solution."

My experience has been that, if the boiling solution becomes too concentrated, there is no precipitation of the cuprous thiocyanate due to its solubility in the concentrated alkaline solution. If water is added to this concentrated solution, as is usually done to keep the volume constant, the white cuprous thiocyanate will be precipitated, depending on the concentration of the solution and the amount of cuprous thiocyanate formed.

The correct end-point is the disappearance of the blue color.

George H. Chapman, B.A.Sc., New York.

DISPENSING NARCOTIC MIXTURES

To the Editor:—A traveling salesman for a pharmaceutical house informs me that a physician who adds a narcotic drug to a cough mixture for administration to one of the physician's patients is liable under the Harrison Narcotic Act to the payment of a tax as a manufacturer. Is this correct? ———, Iowa.

Answer.—No. A physician is authorized to dispense narcotic drugs to patients whom he personally attends. The law does not limit the form in which he may dispense them. The Harrison Narcotic Act defines a manufacturer as one who manufactures or compounds narcotic drugs for sale or distribution.

Infirmary, Brooklyn Hospital and Long Island College Hospital. It also is investigating sterilization and sterility. Under complete medical control, with the endorsement of its plans by the New York Obstetrical Society, the Academy of Medicine and the American Gynecological Society, this committee is furthering and partly financing researches on long range methods of control of ovulation and spermatogenesis as well as the ordinary mechanical handicap methods. Our survey in France demonstrates that its medical profession cannot show what means have curtailed the birth rate; that Holland has not and has never had birth control clinics in any sense in which we use the word clinic, and has not gathered information on the subject, and that the several English clinics, lacking control by any gynecologist or obstetrician of standing, show no follow-up of value. We are, therefore, seeking for trustworthy information from every source, and would prize any returns from clinical studies on "therapeutic contraception" from Rock Island County, or a list of their institutions giving instruction to patients whose life or health would be jeopardized by pregnancy.

.60 grains Extract Cannabis Indica
.075 grains Extract Belladonna
.075 grains Extract Henbane
40 minims Extract Cascara Sagrada
.060 grains Oil Bitter Almonds
5% Alcohol and Aromatic Bitters

Neurosine therefore contains 121 grains of bromid in each fluidounce. When it is considered that the manufacturers recommend "the average dose of Neurosine" as "one dessert spoonful three or four times per diem," the fact appears that the thoughtless prescriber of this nostrum would be giving from approximately 90 to 120 grains (6 to 8 gm.) or more of bromids daily.

Useful Drugs, 1925, states under dosage for potassium bromid, "1 Gm. or 15 grains . . . after meals and at bed time. The dose may be increased to 5 Gm. if a powerful action is indicated." The danger of administering such a preparation as Neurosine without knowing its bromid content is, therefore, readily apparent.

SCOPOLAMIN IN OBSTETRICS

To the Editor—A friendly controversy has occurred in our society as to the wisdom of ever using scopolamin (hyoscin) hydrobromid in obstetric cases. Will you give us your opinion as to the smallest dose that has ever proved fatal, and as to the dose that might ordinarily be expected to be fatal to an adult in good health? Kindly omit name

J. A. R, New Mexico

Answer.—The lethal dose of scopolamin has not been determined for man (Witthaus and Becker). The smallest fatal dose of scopolamin hydrobromid recorded in the literature is 1/100 grain (0 6 mg.). This was given with one-eighth grain (8 mg.) of morphin, and the patient died two hours later (Ely).

Since there is a great difference in the ability of persons to recover from poisoning due to the atropin series, statements regarding "the dose that might ordinarily be expected to be fatal" may be misleading In contrast to Ely's case are the reports of individuals who received as much as one-tenth grain (6 mg., Zimmerman), one-seventh grain (9 mg., Korn) and one-fifth grain (13 mg., Stolle), all of whom recovered.

Regarding the use of scopolamin in obstetric cases, there need be little fear of maternal mortality. De Lee says of scopolamin, "While the life dangers to the mother can be eliminated, the patient must be willing to pay the price of possible lacerations." Williams says, "It [scopolamin] has no effect on the maternal mortality." Haultain gave one patient in labor fifty-three doses of scopolamin, the first dose of which was 1/150 grain (0.4 mg.) and the fifty-two subsequent ones were each 1/450 grain (0 1 mg.). In a series of 1,604 deliveries, Van Hoosen gave twenty patients more than fifteen doses of scopolamin hydrobromid, each dose being 1/100 grain (0.6 mg.). One of these patients received thirty-one doses.

While a moderate number of fatal cases of scopolamin poisoning have been reported in the literature, careful examination of these reports reveals the fact that other drugs and anesthetics were used with the scopolamin and that death in some instances at least was not due to the scopolamin. Nicholson, who gave a kitten 3 grains (0 2 gm.) and a small cur 5 grains (0 3 gm.) of scopolamin without a fatal result, showed experimentally that the toxic doses of scopolamin and morphin correspond very closely to that of morphin alone for the animals used.

PROSTATITIS

To the Editor—I am greatly interested in a case of prostatitis. A man, age 39, had gonorrhea about seventeen years ago, at which time he had an abscess which required catheterization for the urine for several days when the abscess broke into the urethra. Three months before I saw him he was troubled with distress before and during bowel movement, and his condition was diagnosed as a grade 4 prostatitis, seven infected teeth, and a grade 2 infection of the tonsils. Otherwise the examination was negative He was advised to take massages of the prostate, which he has been taking for about three months, with considerable improvement in the symptoms. There is not any physician in any of our neighboring towns or cities that has had any experience with massaging in this condition He was advised to have gentle massages He wonders whether massages given by an inexperienced man might predispose to carcinoma. Have you any statistics to show the frequency of carcinoma following prostatitis? Is it a predisposing factor? Why was gentle massage recommended? Is there anything in diathermy or quartz lamp therapy or in the electrotherapeutic field that has shown good results in these cases? Could the infection have been in his prostate all these years since the gonorrhea? Would you advise exercise for him? If you should answer this in The Journal, please omit my name.

M.D, Wisconsin.

Answer.—There is no tangible evidence that prostatitis is in any causative connection with cancer of this gland.

Brusque massage of the prostate may lead to injury to the glandular tissue and is apt to produce nervous symptoms. Massage of the prostate is safely done by using a club-shaped metallic instrument devised for this purpose. This appliance may be purchased at any medical supply house.

It is highly probable that the condition referred to dates back to the gonorrheal infection.

Diathermy furnishes excellent results in cases of chronic prostatitis It is applied by placing a large indifferent electrode on the abdomen and a prostatic electrode in the rectum. The milliamperage is raised until the patient feels decided warmth but not heat in the rectum, and is maintained at this level during the entire treatment, which should last about twenty minutes These treatments are repeated every third day until the patient is free from all symptoms.

There is no objection to moderate exercise except bicycle or horseback riding

BENEDICT TEST FOR SUGAR

To the Editor—In The Journal, July 11, in reply to an inquiry of Dr George S Silliman regarding Benedict's quantitative test for sugar, you end your reply by stating that "If this white precipitate of cuprous thiocyanate is not obtained, provided glucose is present there is probably something faulty with the solution"

My experience has been that, if the boiling solution becomes too concentrated, there is no precipitation of the cuprous thiocyanate due to its solubility in the concentrated alkaline solution If water is added to this concentrated solution, as is usually done to keep the volume constant, the white cuprous thiocyanate will be precipitated, depending on the concentration of the solution and the amount of cuprous thiocyanate formed.

The correct end point is the disappearance of the blue color.

George H. Chapman, B A.Sc., New York.

DISPENSING NARCOTIC MIXTURES

To the Editor—A traveling salesman for a pharmaceutical house informs me that a physician who adds a narcotic drug to a cough mixture for administration to one of the physician's patients is liable under the Harrison Narcotic Act to the payment of a tax as a manufacturer. Is this correct?

————, Iowa.

Answer.—No. A physician is authorized to dispense narcotic drugs to patients whom he personally attends. The law does not limit the form in which he may dispense them. The Harrison Narcotic Act defines a manufacturer as one who manufactures or compounds narcotic drugs for sale or distribution.

District of Columbia July Examination

Dr. Edgar P. Copeland, secretary, District of Columbia Board of Medical Supervisors, reports the oral and written examination held at Washington, July 14, 1925. The examination covered 16 subjects and included 80 questions. An average of 75 per cent. was required to pass. Fifty-nine candidates were examined, fifty-eight passed and one failed. Four candidates were licensed by reciprocity. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
Georgetown University	(1925, 7)	83.4, 85.2, 86, 87.1, 88, 88.8, 90.9
George Washington University	(1925, 22)	80.3, 80.5, 80.9, 81.3, 81.4, 81.8, 82, 82.4, 82.5, 82.5, 82.9, 84.6, 85.3, 86.3, 86.8, 87, 87.1, 87.9, 89.9, 90, 90.1, 92

Book Notices

An Approach to Social Medicine. By Francis Lee Dunham, M.A., M.D., Lecturer on Social Medicine, Johns Hopkins University. Cloth. Price, $4. Pp. 242, with 10 illustrations. Baltimore: Williams & Wilkins Company, 1925.

Dr. Dunham has had wide experience "as consulting psychiatrist to various civic and private welfare agencies, such as hospitals, bureaus and courts." In the classroom, he has related this experience to the past and the present, and, constructively, to the future. These elements he has compressed into a small book. The subject matter is given in the author's own summary:

> Looking at our subject in retrospect, we find a general interest in conduct, justifying its closer study as a scientific field not inaptly termed Social Medicine. . . . Philosophical, historical and experimental data contribute to an analysis of social problems and suggest ways of harmonizing behavior and of developing conduct. . . . In this development of culture the subject's historical record is utilized as an important technical instrument, revealing ancestral tendencies and personal characteristics relating to health, character and mentality. . . . A biological approach is advocated and the basis and organization of character are considered from four angles, each of which serves to support a typical social group. When correlated with intelligence these groups serve to differentiate four types of social value. . . . Physicochemical energy is recognized as the fundamental cause of social phenomena whose modes of action or forces are connected with the physiological needs of nutrition, protection and perpetuation of species modified by conditions of society. . . . As right slowly supplants might in disposing of social differences, evidence based on experiment takes the place of dogmatic belief. What the individual does must be measured by what he is, the relativity of personality and surroundings tempering our estimate of conduct. . . . Efforts to deal justly with the individual and to protect the group rely greatly upon intelligence and health but mostly upon character, which, as Matthew Arnold often stated, is three fourths of life.

The book deals with a difficult subject and is not easy reading. Involved sentences and frequent Johnsonian diction make it harder than necessary. The following sentence is one of the worst examples:

> As an evolutional consequence of cosmic phenomena man shares with other physical components of his environment, conforming to the theory that "space, time and matter are not independent concepts but are interwoven upon each other," in general probably satisfying the conditions of electrical energy.

Some medical men, furthermore, would consider prophecy strained when Dr. Dunham forecasts that "quantitative estimates of character" may be made by "analyses of glandular secretion and their effects in producing affective phenomena." It is, however, a forward looking, stimulating and essentially sound book; and the first chapter, together with the many record forms of the appendix, make it a practical one as well.

Modern Aspects of Syphilis. By M. J. Horgan, B.A., M.B., B.Ch. Cloth. Price, $1.75. Pp. 136. New York: Oxford University Press, 1923.

This is not a comprehensive treatise, but is a timely presentation of some of the problems of syphilis. Chief attention is given to some of the aspects of cerebrospinal syphilis and its behavior under modern methods of study. Other topics are the pathology of syphilis, nonspecific factors in the control of syphilis, and certain phases of specific therapy.

Physiologie und Pathologie der Leber nach ihrem Heutigen Stande. Von Professor Dr. Franz Fischler. Second edition. Paper. Price, 15 goldmarks. Pp. 310, with 9 illustrations. Berlin: Julius Springer, 1925.

The study of the functions of the liver has always been an interesting subject for investigators. From the time of the crude conception of the functions of the liver held by ancient physicians to that of recent time is a long period of years. The bulk of the information, however, has been obtained only comparatively recently by the aid of the exhaustive experimental study of the type Dr. Fischler has made in the preparation of his monograph on the physiology of the liver. Most of the information has been obtained working with an Eck's fistula or a reversed Eck's fistula, made by an anastomosis of the portal vein and inferior vena cava and the ligation of the vena cava above the anastomosis. Much of the work reported is confirmation of work already done. The rôle of the liver in the metabolism of carbohydrates, fats and proteins, its ability to store these substances, to be drawn on when required, is fully described. He describes a condition of meat intoxication with symptoms of alkalosis in which the liver plays an important part. Another form of intoxication occurs when the body is deprived of carbohydrates. The rôle of the liver in the building up and breaking down of the "bausteine" and disposal of nitrogenous residue is fully described. From a technical and experimental point of view and for workers in this field, this is an excellent presentation of the subject, but for the clinician it is hardly practical. The bibliography is complete.

Clinical Features of Heart Disease. An Interpretation of the Mechanics of Diagnosis for Practitioners. By Leroy Crummer, M.D., Professor of Medicine, University of Nebraska. Introduction by Emanuel Libman, M.D., Physician to Mount Sinai Hospital. Cloth. Price, $3. Pp. 353. New York: Paul B. Hoeber, Inc., 1925.

Appearing at a time when the literature on heart disease is abundant, if not overabundant, this volume, by its balance and perspective, finds a place that has not been filled in American literature. For this reason it is all the more regrettable that the author sometimes permits himself to be more dogmatic than the state of our knowledge warrants. The more critical reader may find also many other places in which he differs in opinion with the author, but where a definitely stated opinion adds to the clarity and the teaching value of the book. The book is purely clinical. The author begins with the methods of diagnosis, considering first of all the importance of an adequate history. Then follow chapters on inspection, palpation, percussion and auscultation. Laboratory methods are left to textbooks dealing especially with those subjects. As the author states, the clinician who understands the physiologic basis of cardiac irregularities can diagnose them clinically at the bedside. A little more detail in places might make the clinical differentiation sharper. Mitral and aortic disease are considered in separate chapters, as is cardiovascular renal disease. The chapter on decompensation is concerned with the symptoms of cardiac insufficiency and their significance. Treatment is discussed, and then follow chapters on cardiac neuroses and cardiac emergencies, in the latter of which angina pectoris is included. The book may be read with profit by any clinician, but can be especially recommended to those in general practice whose training antedated our present conception of heart disease. It will also be of value to students confused by too great wealth of detail, and overemphasis on the importance of laboratory methods.

Mental Derangement Sufficient to Invalidate a Will

(In re Perkins' Estate (Calif.), 235 Pac. R. 45)

The Supreme Court of California, in reversing a judgment that denied the probate of a will, says that not every mental departure from the normal will destroy a testamentary disposition, otherwise valid, of the testator's estate. It is not the rule of law that no person who is insane may make a valid will. The real rule is that the will of a person, who by reason of insanity is incapable of making valid testamentary disposition of his estate, shall not be upheld. Mental derangement sufficient to invalidate a will must be insanity in one of two forms: (1) Insanity of such broad character as to establish mental incompetence generally; or (2) some specific and narrower form of insanity under which the testator is the victim of some hallucination or delusion. Even in the latter class of cases it is not sufficient merely to establish that a testator was the victim of some hallucination or delusion. The evidence must establish that the will itself was the creature or product of such hallucination or delusion; that the hallucination or delusion bore directly on and influenced the creation and terms of the testamentary instrument. The evidence must establish, in addition to the fact of the existence of the hallucinations or delusions, the fact that by reason of these hallucinations or delusions the testator devised or bequeathed his property in a way which, except for the existence of such delusions, he would not have done. In short, the abnormality of mind must have had a direct influence on the testamentary act. Care must be taken to differentiate between mere unreasonable opinions and mental derangements. Testamentary capacity does not depend on the testator's ability to reason logically or on his freedom from prejudice. A belief may be illogical or preposterous, but it is not therefore evidence of insanity.

Physician Keeping Liquor in His Office—"White Mule"

(State v. Ryan (Mo.), 269 S. W. R. 627)

The Springfield (Mo.) Court of Appeals says that it appeared from the evidence that a sheriff who raided the defendant's office found therein about a gallon and a half of alcohol, a quart of red whisky, and a jug which contained one-half pint of what was called "white mule." For the defendant it was shown that he was a regularly registered and practicing physician and had a permit from the county court to issue prescriptions for intoxicating liquor. The defendant testified, and introduced in evidence exhibits to show that he had purchased the liquor under the federal regulations relating to the purchase of liquor by physicians for use in the practice of their profession. He also testified that he bought the liquor for medical purposes. The case was tried on the theory that the fact that the defendant was a physician did not authorize him to keep intoxicating liquor in his office for use in his practice as a physician, the jury being instructed that if it believed from the evidence that he had such intoxicating liquor in his office used by him as a physician, and not in his private residence, it could not acquit him, even though it might find from the testimony that he had secured a permit from the federal government to purchase the liquor for use in prescribing it in his practice as a physician. That instruction was erroneous, in consequence of which a judgment of conviction of the unlawful possession of intoxicating liquor is reversed, the cause being remanded. The court does not think that the provision of the state prohibiton act that a person who has lawfully obtained intoxicating liquor and is using it in a lawful way may keep it in his private residence applies to a physician engaged in the legitimate practice of his profession. If this defendant had the right to prescribe and administer intoxicating liquor either alone or as part of a compound as a medicine, then, of necessity, he must be permitted to possess the liquor to be used for that purpose at his office where he practiced his profession.

But a physician may not use his authority as a physician to cover up violations of the law. His good faith may be inquired into. There was evidence enough in this case to take to the jury the question of the good faith of the defendant and the purpose for which he had the intoxicating liquor in his possession in his office. The sheriff testified that part of the liquor found in the defendant's office was what he called "white mule." This "white mule" was whisky of such a low grade that no reputable physician would either prescribe or dispense it as a medicine. If the defendant had intoxicating liquor in his possession for any purpose other than for legitimate use in the legitimate practice of his profession, he should be convicted. If he kept it in his office in good faith for use in the legitimate practice of his profession, then his possession was lawful, and he should be acquitted.

Promise to Pay for Services for Son and His Old Bill—Impeachment of Witness

(Evans v. Shaw (Texas), 268 S. W. R. 1037)

The Court of Appeals of Texas, in affirming a judgment for $188 in favor of plaintiff Shaw, says that he sued the defendant for that amount for professional services in treating Little Tom Evans and his wife, Little Tom Evans being an adult son of defendant Evans. The plaintiff alleged that, being called to see Little Tom, he found him suffering with a severe attack of pneumonia, and that as Little Tom had not paid his bill of $102 for treatments of himself and wife in the previous year, the plaintiff informed defendant Evans that unless the latter would agree to pay, not only for his services from that date, but also the old bill of $102, he would not treat Little Tom any further, to make which payments the defendant then agreed; that if the defendant had not made the promise, he would not have treated Little Tom during his last sickness; and that his charges for such treatment amounted to $86, making the total sum sued for $188. The defendant denied that he had ever made any such agreement with the plaintiff as was alleged, and that, if any such agreement was made, it, not being in writing, was void under the statute of frauds. The verdict of the jury for the plaintiff is interpreted as a finding that the defendant did make the agreement alleged, although the evidence as to whether he did or not was sufficient to sustain a finding either way.

As to the $86 of the account, the plaintiff, in treating Little Tom, was extending credit to the defendant, and the defendant's obligation to pay was an original primary obligation. It was the defendant's own debt, and the promise to pay for the services rendered after the promise was made never at any time came within the purview of the statute of frauds requiring a promise to answer for the debt of another, or a memorandum of the promise, to be in writing signed by the person to be charged therewith or by some one by him thereunto authorized. Clearly the plaintiff was entitled to recover, under the findings of the jury, this much of the account sued on.

For the treatments for which the $102 was charged, the plaintiff extended credit solely to Little Tom Evans, and this much of the account was a debt against him alone, and continued a debt against him alone up to and at the time of the defendant's verbal agreement to pay it. Was the defendant's promise to pay this part of the debt within the statute? This question required a good deal of research. It was true that Little Tom Evans was an adult son of the defendant, 25 years of age, not dependent on the defendant, nor a member of his family, and there was no legal obligation on the part of the defendant to furnish him medical treatment; but, at the time of the conversation between the defendant and the plaintiff, the defendant's son was a very sick man, and died a few days later. The son was in a helpless condition, unable on his own responsibility to secure treatment by the plaintiff. There was a moral obligation and duty on the part of the defendant to secure such treatment, and no doubt the defendant felt very keenly this moral obligation on his part, and so, for the purpose, not primarily, of paying or securing his son's debt, but to subserve a purpose of his own—the performance of this moral obligation to his son—he agreed unconditionally to pay, not only for future treatments, but also the old bill of $102. The promise of the defendant having been made by him to subserve a purpose of his own, and not primarily to settle his son's debt, such promise was not within the statute of frauds, and created a primary obligation on the part of the defendant for the $102, as well as for the future treatments.

The defendant complained of the action of the trial court in permitting the plaintiff to impeach the testimony of a witness for the defendant by showing, on cross-examination, that the witness had taken chloroform in an attempted suicide, and that the witness still owed the plaintiff for services rendered him at that time. This assignment of error was not properly presented, but the court will say that, if it were to consider this assignment, it would be compelled to overrule it, as it presented no error.

Reference by Expert Witness to Statistics

(Forrest v. Fink (Calif.), 234 Pac. R. 860)

The District Court of Appeal of California, First District, Division 1, says that in this action to recover damages for personal injuries a medical witness was asked: "Have you made a study of the statistics relative to brain tumors, the percentage of cases of brain tumor which give a previous history of either a fracture of the skull or brain injury?" His answer was: "Yes, 27 per cent. of them give a history of such injury." Later the witness said: "Well, of course, he may get over this. The chances are two to one from statistics that I have already quoted that he will not. He may go on the way he is now, and he may get a good deal worse." It was contended that the physician, instead of giving his own opinion, fortifying it by his reading, if he wished, based his entire answer on the statistics, which were admittedly hearsay. But the court does not think that there was any error in permitting the witness to testify as to what statistics showed concerning the result of injuries received similar to those received by the plaintiff. A witness to qualify as an expert must show himself to be skilled in his business or profession, but there is no precise rule as to how that skill must be acquired. He may be an expert through knowledge derived from the study of the subject only. An expert witness might reasonably be expected to rely, to a great extent, on the statistics he has studied, which must be taken into consideration with his observation and experience. In the case at bar the witness referred to statistics. The court feels that the situation here was entirely different from allowing medical or scientific books to be read to the jury or seeking to influence them by opinions or theories contained in such books. His answer must be assumed to have been a conclusion reached by him after a judicious comparison of all that he had read or learned on the subject, and on his opinion as well as its source, he could be subjected to the most rigid cross-examination. A hearing was denied by the Supreme Court of California.

Society Proceedings

COMING MEETINGS

American Academy of Ophthalmology and Otolaryngology, Chicago, Oct. 20-24. Dr. Luther C. Peter, Chestnut and 20th Streets, Philadelphia, Secretary.
American Association of Railway Surgeons, Chicago, Oct. 21-23. Dr. Louis J. Mitchell, 29 East Madison Street, Chicago, Secretary.
American College of Radiology and Physiotherapy, Chicago, Oct. 19-22. Dr. Roy W. Fouts, 121 South 33d Street, Omaha, Neb., Secretary.
American College of Surgeons, Philadelphia, Oct. 26-30. Dr. Franklin H. Martin, 40 East Erie Street, Chicago, Director-General.
American Public Health Association, St. Louis, Oct. 19-22. Mr. Homer N. Calver, 370 Seventh Avenue, New York, Executive Secretary.
Central Neuropsychiatric Association, Ann Arbor, Oct. 23-24. Dr. Karl A. Menninger, Neuropsychiatric Clinic, Topeka, Kan., Secretary.
Central States Pediatric Society, Chicago, November 6-7. Dr. H. T. Price, Westinghouse Building, Pittsburgh, Secretary.
Delaware State Medical Society, Wilmington, Oct. 13-14. Dr. W. O. La Motte, Industrial Trust Building, Wilmington, Secretary.
District of Columbia, Medical Society of, Washington, D. C., Dec. 2. Dr. C. B. Conklin, 500 Medical Science Bldg., Washington, D. C., Sec'y.

Vermont State Medical Society, St. Johnsbury, Oct. 15-16. Dr. William G. Ricker, 29 Main Street, St. Johnsbury, Secretary.
Virginia, Medical Society of, Richmond, Oct. 13-16. Miss Agnes V. Edwards, 104½ West Grace Street, Richmond, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal for a period of three days. No foreign journals are available prior to 1920, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

American Journal of Medical Sciences, Philadelphia

170: 157-312 (Aug.) 1925

*Clinical Value of Ephedrin. T. G. Miller, Philadelphia.—p. 157.
*One Hundred Consecutive Cholecystectomies. W. O. Johnson, Cleveland.—p. 181.
*Twenty-Eight Cases of Purpura Hemorrhagica in Which Splenectomy Was Performed. H. Z. Giffin and J. K. Holloway, Rochester, Minn. —p. 186.
*Clinical Study of Quinidin Therapy. H. H. Riecker, New York.—p. 205.
*Experimental Gastric and Duodenal Inflammation and Ulcer. A. Hoffmann, Anaheim, Calif.—p. 212.
Sigmoidoscopic Picture of Chronic Ulcerative Colitis (Nonspecific). B. B. Crohn and H. Rosenberg, New York.—p. 220.
Possible Relationship Between Guanidin and High Blood Pressure. R. H. Major, Kansas City, Kan.—p. 229.
*Calorimetric Studies of Extremities Following Lumbar Sympathetic Ramisection and Ganglionectomy. G. E. Brown and A. W. Adson, Rochester, Minn.—p. 232.
*Diseases of Coronary Arteries. M. H. Nathanson, Minneapolis.—p. 240.
*Rectal Ether Analgesia in Childbirth. J. A. Harrar, New York.—p. 256.
Diaphragmatic Hernia of Cardia of Stomach Through Esophageal Orifice. J. Friedenwald and M. Feldman, Baltimore.—p. 263.
*Iodin Hyperthyroidism. A. S. Jackson, Madison, Wis.—p. 271.

Ephedrin.—Ephedrin is the name given to an active principle of an Asiatic drug *Ma Huang (Ephedra vulgaria* var. helvetica), which has been used in the practice of medicine in China for more than 5,000 years. Ephedrin has general physiologic effects in man similar to those produced by epinephrin. It has, however, distinct practical advantages over epinephrin because of its more prolonged action and the fact that it can be administered affectively by mouth. Miller reports his clinical observations with this drug. In doses of from 50 to 125 mg., given orally or subcutaneously, ephedrin sulphate usually raises the systolic and diastolic blood pressure and decreases the pulse rate for a period of several hours. It also stimulates the heart action and has a tendency to increase the output of urine. It sometimes increases the basal metabolism. Its administration caused temporary improvement in two cases of Addison's disease, gave relief in the paroxysmal attacks of certain cases of asthma, relieved the subjective sensations in a case of urticaria, caused a disappearance of urticarial lesions in a case of serum disease, and produced marked temporary improvement in a case of circulatory failure incident to myocardial disease and the evacuation of an overfilled urinary bladder. In a single case of complete heart block it produced an increase in both the auricular and the ventricular rates and caused alterations in the character of the electrocardiographic tracings. Locally applied to the nasal mucous membrane, ephedrin causes prompt contraction which persists for more than three hours and has no local irritant effect. It is believed that the wide range of usefulness of ephedrin will be found in the treatment of asthma and of acute circulatory depression, and in the management of certain congestive nasal conditions.

Bacteriology of Gallbladder Diseases.—A bacteriologic and histologic study was made by Johnson of 100 cases of gallbladder lesions together with a histologic study of the associated appendixes. Organisms were cultured from the fluid contents of pathologic gallbladders in less than one third of the cases in this series. *B. coli* was the predominating organism in the positive cultures. The highest percentage of positive cultures was obtained from the gallbladders which contained the lowest percentage of bile salts. Even after double ligation of the cystic duct there was an escape of bile in two cases, a finding which reinforces the argument for drainage of the abdomen after cholecystectomy. Histologic changes seem to indicate that the lesions in the appendix are of longer duration than the other associated gallbladder lesions. Histologically, pathologic gallbladders with culturable organisms in their fluid content, have a far higher mucus content than normal gallbladders. The walls show an increase in fat content and thickening.

Purpura Hemorrhagica with Splenectomy.—In six of the twenty-six cases analyzed by Giffin and Holloway slight epistaxis occurred chiefly during the first few days after operation. In all cases, so far as can be ascertained, these slight evidences of the hemorrhagic tendency were transient. Their appearance suggests the possibility that foci of infection might still be present in these cases. The logical procedure in cases of purpura hemorrhagica would seem to be a splenectomy followed by elimination of all possible foci; the latter portion of the treatment cannot be safely neglected. In most of the cases before operation, at some time in the course of each case, the platelets numbered less than 50,000. In a few instances the counts were in the hundreds. After operation the platelets almost always rose rapidly to above normal, and in three instances more than 1,000,000 are recorded. In two instances they remained below 50,000 but even in these cases the ultimate results were satisfactory. The facts indicate that the increased number of platelets is only one factor in the arrest of purpuric manifestations. The tourniquet test was always positive when applied during active periods of purpura and not infrequently during remissions. After operation it became negative soon after the petechiae and ecchymoses faded. In many of the cases the bleeding time was longer than eight minutes and occasionally longer than one hour, although not infrequently it was approximately five or six minutes. After splenectomy there was great variability in the promptness with which the bleeding time became reduced. In three cases it is reported as normal within a few hours. In most of the cases it became reduced quite promptly to less than eight minutes, and in from five to eighteen days to less than three minutes. The recurrence of petechiae in some of the cases, the slowness with which the bleeding time becomes reduced, and the variability in connection with the recovery of the retractility of the clot, indicate that although a change has been brought about by splenectomy sufficient to arrest gross hemorrhage, the finer mechanism of coagulation requires a complex readjustment on the part of the organism, which may or may not become complete and permanent. A few of the patients have remained somewhat anemic. However, the uniformly good results indicate at least a temporary cure.

Quinidin Therapy.—Riecker reports fifty-two cases of auricular fibrillation with restoration of the normal rhythm in 79 per cent. following quinidin therapy. He describes in detail the method employed. The use of quinidin sulphate is justified and seems indicated in all cases of auricular fibrillation, except in those in which there are signs of recent embolism, marked decompensation of the heart or early appearance of the symptoms of cinchonism. Both the temporary and permanent conversion of the fibrillation to a normal sinus rhythm by the drug seems to be favorably influenced by the presence of a delayed conduction time at the auriculoventricular junction. The careful management of cases with regard to exercise, mental excitement and fever during quinidin administration greatly facilitates the favorable action of the drug. The administration of quinidin is most effectual when given continuously through the day and night as suggested by Lewis. The use of digatalis to maintain the rhythm after its conversion seems to be even more important than that of quinidin in chronic auricular fibrillation.

Bacteriology of Peptic Ulcer.—Hoffmann describes the morphology, isolation and recovery, cultural characteristics and pathogenicity, in the guinea-pig, of an organism isolated from the stomach contents of two patients, diagnosed as having gastric or duodenal ulcer, and from tonsil emulsion of a third patient, who also was believed to have a gastric or duodenal ulcer. Guinea-pigs inoculated with the specific organism, intra-abdominally or intramuscularly, showed lesions in the duodenum or stomach, or both, in which the bacillus was demonstrated. Sterile filtrates of the specific organism produced the same lesions as when the organism itself was used.

Lumbar Sympathetic Ramisection and Ganglionectomy.—Five cases of spastic paraplegia are reported by Brown and Adson in which bilateral lumbar sympathetic ramisection and ganglionectomy was performed. The second, third and fourth lumbar ganglions with the sympathetic trunk were removed and the rami divided. During the postoperative period marked increase in the skin temperature of the legs and feet was observed. Calorimetric studies with the foot calorimeter demonstrated marked increased heat production and heat radiation. There was complete absence of sweating in the legs in two cases. The vasomotor dilatation in the lower extremities, indicated by the calorimetric studies, was borne out by the clinical observations in respect to increased heat of the skin.

Clinical Picture of Coronary Sclerosis.—An attempt was made by Nathanson to construct a clinical picture of coronary sclerosis by an analysis of a series of fatal cases which came to necropsy. The following points are brought out by this study: Coronary sclerosis is most common in males and in the age period between 50 and 70 years. The outstanding clinical feature is the presence of attacks, usually of pain, less frequently of acute respiratory distress. The pain is most often in the chest, but abdominal attacks are not uncommon. These attacks occur with either of the following combinations: (*a*) normal sized heart, with no evidence of cardiac failure, 37.2 per cent.; (*b*) normal sized heart, cardiac failure present, 2.6 per cent.; (*c*) cardiac enlargement, congestive failure present, 38 per cent. The clinical features of coronary thrombosis are essentially similar to those of coronary sclerosis; thrombosis, therefore, should not be considered as a clinical entity but merely as a complication of coronary sclerosis. The outstanding pathologic features are the following: Changes in the coronary arteries are most marked in the left branch. In addition to coronary sclerosis, thrombosis occurs in approximately one fifth of the cases. Myocardial involvement paralleling the degree of coronary sclerosis is a constant finding. Lesions in the aorta of any significance are present in but a small percentage.

Rectal Ether Analgesia in Childbirth.—Harrar is convinced that rectal ether anesthesia is the safest and most effective method for the relief of the pains of childbirth over a period of hours that has so far been devised. Its applicability is much greater than that of scopolamin amnesia. It can be used safely and effectively by the physicians in home confinements, and does not require the services of a trained anesthetist. The drugs required, morphin, magnesium sulphate, ether and quinin, are easily obtained and well known in their action. The quinin is found to be an essential ingredient in the rectal instillation formula. The only contraindication to the procedure is uterine inertia, and the only restriction is not to start too soon. The woman must be in active labor, that is, pains every five minutes, last forty seconds by the watch, and in a primipara preferably the cervix should have attained a dilatation of two or more finger tips. The mechanism of labor must be as closely followed by the obstetrician as if no analgesia were being employed.

Iodin Hyperthyroidism.—The popular enthusiasm which has supported the prophylactic treatment of simple colloid goiter, together with the discovery of the efficacy of iodin in the treatment of exophthalmic goiter, Jackson says, has greatly increased the number of cases of iodin hyperthyroidism. He has seen thirty-eight cases in two years. If an early diagnosis is made, medical treatment may abort the toxic symptoms. Thyroidectomy is indicated when the condition does not yield to medical measures. The pathologic picture is not characteristic. Grossly, the gland has the typical appearance of an adenomatous goiter containing degenerated, cystic, fibrous and calcareous encapsulated nodules. Colloid may be seen in large amounts. The microscopic picture shows acini of variable size, lined with flat, cuboid cells and filled with colloid. Fetal acini and occasional small areas of hypertrophic cells are found.

Twenty-Seventh Report of Progress in Orthopedic Surgery. N. Allison et al., Boston.—p. 473.

Chronic Subdural Hematoma.—Putnam discusses the pathology of these tumors, their relation to pachymeningitis and their surgical treatment. Eleven cases are reported, an analysis of which shows that an apparently insignificant trauma to the head may, in certain persons, be followed, after a latent interval which varies from a few hours to months or even years, by symptoms of cortical irritation and of intracranial pressure due to a subdural hematoma. These cases are less rare than was formerly supposed. Clinically, after a period of headache, these patients show an extraordinary variability of symptoms, particularly in the intellectual sphere. They are prone to psychoses and often become irritable, indecent and unmanageable. Choked disk is apt to be present and a frontal lobe tumor suspected. At operation or necropsy, a subdural hematoma will be found, on one or both sides, enclosed in a continuous membrane slightly adhering to the dura but not adherent to the arachnoid. In certain cases in which the onset of symptoms is delayed for only a few days after trauma, it is possible that they may be due to a hematoma formed immediately but which only announces its presence when the brain becomes edematous or congested. In other cases the occurrence of late hemorrhages seems probable and may be due to the formation of communication between the mesothelium lined spaces and blood vessels, with rupture of one or the other. When the presence of a subdural hematoma is under suspicion, the exploratory craniodural puncture over the hemisphere will give the most reliable evidence of the presence or otherwise of the clot. If the diagnosis is verified, an osteoplastic resection with reflection of the dura and removal of the more or less organized clot as intact as possible is the procedure of choice, with subsequent painstaking hemostasis. The removal of the dura on the basis that it is a possible source of further hemorrhage is unnecessary. Experience tends to show that there need be no fear of reformation of the clot but that cerebral edema is apt to occur in the brain released from its long pressure. It consequently may be advisable to combine the osteoplastic exploration with a subtemporal decompression. Should edema occur, the use of hypertonic saline solution or the performance of lumbar puncture should, perhaps, be resorted to before reinvestigation of the wound, for in no case in the present series, at least, has the procedure been of use.

Localization of Lung Abscess.—By the employment of the Hirtz compass for localization in three cases of lung abscess, Sante and Lehman have been enabled on the operating table to enter the cavity of the abscess with the exploring needle at the first attempt.

Sequelae of Rectal Implantation of Ureters for Exstrophy.—Fourteen years ago the Bergenhem operation was performed on a boy, aged 3 years. Nothing of a serious nature happened until twelve years later, when the boy presented himself with a left-sided pyonephrosis and perinephric abscess, which was drained. In May, 1922, almost fourteen years after the rectal implantation of the ureters, he returned again with a similar lesion on the right side. This, too, was drained. The patient died four days later. Richey reports the necropsy findings. That the ascending type of renal infection is an entity would seem to be clearly indicated in this case, in which the sequence of pathologic changes evidently was ureteritis, pyelitis, pyelonephritis, pyonephrosis and perinephric abscess, with and without calculus formation. However, inasmuch as there was plenty of damage in all coats of the ureteral wall and the renal pelvis, and a marked inflammatory involvement of the perivascular lymphatics in these structures, Richey is at a loss to ascribe the pathway of infection to a single anatomic structure.

Congenital Abnormalities of Intestine.—Farr and Brunkow discuss intestinal aplasia and atresia of the rectum and anus complicated by rectovesical fistula, and report one case of each.

Fracture of Skull.—Rand and Nielsen present the results of an analysis of 171 proved cases of fracture of the skull with a mortality of 25.7 per cent. Thirty-eight patients (22.2 per cent.) were operated on, with an operative mortality of 47.7 per cent. Sixty-eight per cent. of the deaths occurred within forty-eight hours after injury. All the deaths after the fifth day were due to complications, viz., septicemia, brain abscess or meningitis, with exceptionally a subdural hemorrhage of many months' standing. In one case of proved meningitis (*Bacillus mucosus-capsulatus* of Friedländer), the patient recovered after four intravenous injections of 30 c.c. of 1 per cent. solution of mercurochrome-220 soluble and repeated lumbar punctures.

*Gas Bacillus Infection with Perforated Gastric Ulcer. N. A. Dayton, Wrentham.—p. 507.
Progress in Pulmonary Tuberculosis. J. B. Dawes, 2nd, Boston.—p. 508.

Use of Iodin in Goiter.—Since the employment of compound solution of potassium iodid, Lahey has observed a higher percentage of myxedema following subtotal thyroidectomy than was the case before its use, a situation which he believes is entirely explained by the fact that the type of thyroid tissue remaining after thyroidectomy in patients who have had this treatment is much less active than that left in patients who have not had it. The section coming from the same amount of remaining tissue in these two types is quite different, and with these facts in mind it is necessary to leave behind somewhat more of the iodin converted tissue in the hyperplastic goiter than was the custom previous to its employment to insure an adequate supply of thyroid secretion. Lahey deprecates the widespread use of iodin in these cases without adequate knowledge of its action. Iodin is useful in two pathologic thyroid states—one, in regions where goiter is endemic, and the iodin content of the drinking water is low, as a prophylactic measure against the development of goiter in children; and two as a measure to prepare toxic thyroid patients for operation.

Gas Bacillus Infection with Perforated Gastric Ulcer.—Dayton relates the case of a male, aged 18, an imbecile who contracted a gas bacillus infection by way of a gastric ulcer. Death occurred five hours after the patient first complained of not feeling well. Puffiness of the neck first was noted twenty-five minutes before death. This condition spread rapidly, and the skin became tense and drumlike as the tissues were ballooned out. Synchronously, the superficial structures of the abdomen began to puff. The dirty gray color of the skin gave away to a light brownish tinge. The patient took a sudden deep inspiration and died. Rapid involvement of the entire body then took place, tremendous gaseous distension of the skin of the face, scalp, arms, chest, penis, scrotum and thighs occurring within an hour. The necropsy disclosed a ruptured gastric ulcer with escape of contents of stomach to the peritoneal cavity; infection of blood stream with *Bacillus aerogenes-capsulatus.*

Low Back Pain.—From his analysis of 200 cases, and from anatomic investigations preceding the cases analyzed, Steindler believes that sacro-iliac as well as sacrolumbar sprains are distinct clinical entities of injuries to the ligamentous apparatus of these regions and their neighborhood, subject to the same laws that obtain in other ligamentous sprains in the body. The anatomic relationship of this ligamentous apparatus to certain structures of the pelvis especially the nerve plexuses and the neighboring bones, makes for a certain regularity of symptoms which aid very considerably in the exact diagnosis. Among these are first, more or less typical postures, especially lateral tilts and lumbar lordosis; then certain typical radiation of pain in the lumbar plexus on one, and the sciatic and the sympathetic plexus on the other hand, producing nervous symptoms, some of which are known as Bertolotti's syndrome. The great percentage of symmetrical positions, on one hand, and of the absence of nervous complications on the other hand, show that neither position nor radiation is necessarily pathognomonic for sacro-iliac or sacrolumbar strain, while the type of radiation and the type of faulty position, if present, are of a definite diagnostic importance. Lastly, anatomic variations do not always, nor even in the majority of cases, form the background of the sacro-iliac or sacrolumbar sprains. On the other hand, however, backs endowed with certain anatomic variations show percentage rates which lead to the conclusion that such backs are inherently weak by virtue of the natural restrictions of the normal motion, and that their possessors are especially susceptible to ligamentous sprains in the sacro-iliac and sacrolumbar evaluation of the function of the back from the point of view of industrial surgery.

Acriviolet Treatment of Ear Infection.—Pearson does not regard acriviolet as a panacea which will supplant proper drainage or removal of diseased tissue. Nor will it make it possible always to get a perfect result with or without operative work. He is using it in all cases of chronic otorrhea which do not demand immediate operation, but has not used it long enough to feel sure that the cases that have dried up are going to stay dry. It has faciliated clearing up an infective process more than any other solution used in cases in which there is good drainage, and no large area of necrotic tissue, that is where it has access to the infection. Acriviolet is nontoxic, absolutely nonirritating and not inhibiting the phagocytic action of the leukocytes nor retarding the healing process unless a large amount of granulation tissue is to be thrown out.

Journal of Clinical Investigation, Baltimore

1: *497-606 (Aug.) 1925*

- *Mechanism of Death from Quinidin; Method of Resuscitation. B. Gordon, M. Matton and S. A. Levine, Boston.—p. 497.

- Effects of Changes in Hydrogen Ion Concentration on Blood Flow of Morphinized Dogs. T. R. Harrison, C. P. Wilson and A. Blalock, Baltimore.—p. 547.

Mechanism of Death from Quinidin.—As a result of experiments on cats, Gordon, Matton and Levine found that the minimal lethal dose of quinidin bisulphate was dependent on the speed of administration. Whereas 25 mg. per kilogram was usually fatal when given in a single dose, on the other hand, when smaller doses were given at intervals of from six to twelve or twenty-four minutes, the total minimal lethal dose correspondingly increased to about 0.1 gm. per kilogram. Immediately following injections of nonlethal doses of quinidin, there was a striking fall in blood pressure. This began a few seconds after the administration was started. The effect on the respiration was directly proportional to the size of the dose. In giving a small dose the breathing was essentially unaffected, whereas after a moderate dose, there was usually a temporary, very brief cessation of the respirations. With increasing sublethal doses there was a slowing of the rate and a decrease in the depth of the respirations. With lethal doses the breathing gradually failed and finally ceased. The heart always continued to beat after complete respiratory failure, for even as long as two minutes. The appearance of the animals under quinidin intoxication was not unlike that manifested by a fatal case in the clinic. It was found that when animals were given lethal doses and the respirations had ceased for a period of one to two minutes, they could be revived satisfactorily by artificial respiration combined with the use of caffein sodium benzoate. The caffein alone was frequently sufficient, although artificial respiration alone was much more effective. When the two procedures were combined recovery took place more rapidly. Roentgenograms taken at frequent intervals during the fall of pressure after an injection of a moderately large dose of quinidin showed at first a slight contraction of the heart followed by a dilatation. With small doses a contraction but no dilatation occurred. There was a marked dilatation as a terminal event. It is suggested that the method of resuscitation employed in reviving the animals in these experiments may be applicable in the clinic in the treatment of quinidin intoxications.

Blood Destruction in Experimental Plethora.—Various hypotheses to explain the blood destruction following experimental plethora were tested by Julianelle and Pons by a number of methods. No evidence was obtained that the blood destruction is the result of the development of isohemolysins. No evidence was obtained to show that this result is due to greater activity of hemophages. The explanation of postplethoric anemia must await further work.

- Complete Bilateral Duplication of Ureters and Renal Pelvis. D. Geiringer and J. Campuzano, New York.—p. 193.

Congenital Valvular Obstruction of Urethra.—Hinman and Kutzmann report six cases in which the diagnosis was made during life by means of the cystoscope. Four cases occurred under the age of 10 years (2, 4 and 6½ years), while the remaining two patients were 18 and 57 years, respectively. The initial symptom in all cases was urinary disturbance, particularly difficulty, and the acuteness and severity of the onset seemed dependent on the degree of infection present. In only one case did the symptoms date back to birth while the shortest duration of symptoms was two weeks. The longest complaint covers ten years. In this case, and one other, the urinary obstruction had sufficiently injured the kidneys to produce uremia, of which one patient died. The urographic studies were usually quite characteristic. A small hypertrophied bladder with hydronephrosis and hydro-ureter, either unilateral or bilateral, as demonstrated by simple cystography, in young boys is almost pathognomonic.

Removal of Ureteral Stone Through Vagina.—Lower advocates the vaginal route for the removal of stones from the lower portion of the ureter for the following reasons: (1) It is a comparatively simple method of removing a stone from a location which is often by other methods very difficult. (2) It affords dependent drainage, should there be leakage. (3) It avoids an external incision. (4) It shortens the period of convalescence.

Hexylresorcinol in Urinary Infections.— Experience with hexylresorcinol in fifty cases has convinced Henline that it is an effective internal urinary antiseptic administrable by mouth, nontoxic, nonirritating to the urinary tract, and a valuable aid in the treatment of urinary tract infections. It is apparently superior to all other urinary antiseptics. Hexylresorcinol, by thorough disinfection of the urinary tract, is an aid in preventing recurrent stones. In postoperative urologic cases, hexylresorcinol is an aid in healing wounds in streptococcus infections.

Mercurochrome as Skin Disinfectant.—The alcohol-acetone-aqueous solution of mercurochrome-220 soluble, made by dissolving 2 gm. mercurochrome in 35 c.c. of distilled water and then adding 55 c.c. of 95 per cent. alcohol and 10 c.c. of acetone, is recommended by Scott and Hill as a very efficient preoperative skin disinfectant. Better skin sterilization is obtained with it than with iodin, potassium mercuric iodid and picric acid. Its application is accompanied by no pain and is, therefore, of special value in operations done under local anesthesia. Regardless of the age of the patient or location of the operative field, no instances of dermatitis have occurred following its use. The solution penetrates more deeply than iodin and potassium mercuric iodid. It penetrates at least as deeply as picric acid and seems to be a little more uniformly distributed at its lower level of penetration. It retains its high bactericidal properties at least forty-six days. It has a relatively low toxicity. The color of the preparation is such that there can be no doubt as to the extent and thorough preparation of the operative field. It should not be objectionable on account of its stain because the solution completely dries on skin in less than two minutes. Any stains accidently obtained are readily removed by surgical solution of chlorinated soda.

Priapism of Long Duration.—Wilson and Maus report a case of priapism of forty-five days' duration, which was due to a lesion of the conus. On the thirty-first day of the priapism, the man was given spinal anesthesia which was successful as far as the anesthesia was concerned but it had no effect on the erection. On the thirty-fifth day the man was etherized and this produced no effect on the priapism. An incision was then made through the skin at the right lateral margin near the base of the penis and was continued through the corpus cavernosum, septum and into the left corpus. A considerable amount of dark blood and several small clots were evacuated. This had no effect on the state of the penis. Two days later, under ether, a second incision was made at the left lateral margin opposite that made previously and rubber tissue drainage was inserted through the wounds. Five days after the second operation, the penis was semiflaccid distal to the incision but was spastic proximally. The erection slowly subsided so that at the end of forty-five days it approached the normal, although it was not entirely flaccid. One year later the penis was flaccid and sexual desire and power had not returned.

Appendicitis in Aged.—Maes states that appendicular disease is relatively infrequent in patients over 50 years of age but is accompanied by a very high mortality. After the thirtieth year the histology of the appendix, as of the tonsil, changes, and to this change may be attributed the early thrombophlebitis and the massive gangrene so frequently found at operation or at necropsy. The objective symptoms give no hint of the gravity of the intra-abdominal pathology, and the naturally lowered resistance of elderly persons, plus organic disease of the heart or kidneys, makes the prognosis always a serious one. Ileus, pyemia and septicemia are frequent complications. Early diagnosis and prompt treatment, in which free drainage is of prime importance, furnish the only possible means of reducing the mortality. Since patients who develop fecal fistulas usually recover, and since a late enterostomy usually does little good, it is suggested that a Pezzer catheter or a Paul tube be left in the cecum at the time of operation.

Tumors Among Filipinos.—Mendoza-Guazon corroborates the statement that tumors are infrequent in the tropics. In the study of the anatomico-pathologic lesions in 1,000 Filipino children under 5 years of age, he found six cases of tumor—two of glioma of the eye; one of fibroma of the capsule of the liver; one of adenoma of the intestine; one of neuroblastoma of the suprarenal; and another of adenoma of the intestine and edematous myoma of the heart. He has encountered only one case of melanosarcoma, with metastasis in the brain, lungs, kidneys, liver, suprarenals, stomach and intestines, in a Filipino.

Abdominoscopy.—Abdominoscopy represents the endoscopic method of examining the abdominal cavity, a method which is not utilized as much as it deserves. Such endoscopy, if carefully executed, is a relatively simple and safe procedure. Originally devised and applied by Kelling, about twenty-five years ago, the method in its technical details has been but slightly modified by subsequent work. At least twenty-five investigators or observers have published work concerning it. The technic as described consists in producing a preliminary pneumoperitoneum, passing a trocar through the locally anesthetized abdominal wall, and on its withdrawal leaving in place a flexible and air-tight sheath. This cannula then permits the introduction of any type of cystoscope preferred by the observer—an instrument either straight or curved, and adapted for either direct or indirect vision. With the cystoscope, an excellent view may be obtained of the interior of the abdomen, particularly in the region of the stomach, liver and bile tracts, and in the pelvic region. The kinds of operative or therapeutic measures performed with the guidance of the cystoscope in the urinary bladder may also be carried out in the abdomen. In some cases peritoneal adhesions form the chief drawback to the employment of abdominoscopy. The diagnostician using the method must be familiar with cystoscopy, and with the normal and pathologic topography of the abdomen. Nadeau and Kampmeier are convinced of the great practical possibilities inherent in this method, and recommend its wider use in clinical as well as in experimental work.

Kidney Tumors.—Hyman analyzes seventy kidney tumors. Hypernephroma occurred forty-four times; mixed tumors ten times; carcinoma twelve times. Hematuria and pain were the most prominent symptoms. Of sixty adult patients, hematuria was noted first in twenty-one instances. Pain as an initial symptom was present eighteen times, and not infrequently antedated the appearance of hematuria by many months, and in a few instances, years. Pain and hematuria appeared simultaneously seven times. Loss of weight was noted in at least 33 per cent. of cases. In five patients, this was the only symptom observed for some time previous to the appearance of any of the classical signs. Cachexia, generally a late manifestation, was present fifteen times; most of these cases had advanced lesions with metastases. Twelve patients, or 20 per cent., already had metastases when first observed. The ultimate mortality ranges between 65 and 75 per cent. and the only way to effect a reduction of this high rate at present, Hyman says, would be to use the cystoscope and make pyelograms, not alone in every case of hematuria, but in every case in which the patient complains of lumbar pain for which no definite cause can be found, and to examine more carefully patients complaining of intractable sciatica and lumbago.

Noncarcinomatous Tumors of Stomach.—A series of noncarcinomatous tumors of the stomach is reported by Meyer and Brams consisting of one myofibroma, two polyps, one adenoma en nappe, one hypertrophic pyloric stenosis in an adult, and mention is made of certain inflammatory conditions, namely, syphilis of the stomach and inflammatory pancreatitis associated with chronic peptic ulcer. Recognition of these tumors and prompt surgical treatment may not only cure the conditions, but may also prevent the occurrence of the serious complications sometimes caused by benign growths of the stomach.

Congenital Salivary Fistula of Neck.—The outstanding features of the case reported by Smith and Torgerson are: (1) The presence of the duct since birth with the absence of infection or swelling. Thyroglossal ducts are usually closed at birth and later swell and rupture. (2) The absence of ciliated columnar epithelium lining the duct. (3) The history of increased flow of its secretion when eating or thinking of food. (4) The finding microscopically of salivary gland tissue. (5) A groove in the mandible. This indicated that the duct must have been present during early fetal life. (6) The presence of cartilage in an unusual location. This would tend to substantiate the teratoid nature of the whole structure.

Rupture of Spleen.—In Jackson's case twenty-eight days elapsed from the time of the initial injury until the appearance of the profound symptoms presented.

Degeneration of Uterine Fibromyoma.—Gross degeneration occurs in approximately 13 per cent. of fibromyomas. Two hundred specimens of grossly degenerated fibromyomas of the uterus were reviewed by Seed and the degeneration classified as follows: hyaline, 24 cases; edematous, cystic, and myxomatous, 80; red degeneration with total necrosis, 33; calcification, 39; infected, subserous and interstitial 3, and submucous, 13; miscellaneous, thrombotic sinus, 5, tuberculous, 1, and fibrolipomatous, 2.

Treatment of Empyema.—Cameron states that in the case of young children and in certain influenzal cases it may be wiser to withhold operation until after the termination of the pneumonia but does not contradict the general rule that any delay in operating makes it increasingly likely that the formation of fibrous tissue in the pleura will prevent or make difficult the proper expansion of the lung. Drainage must be adequate and the opening suitably placed. It is probable that secondary infection is not uncommon. Moist antiseptic dressings offer obvious advantages over sterile pads, both in preventing accidental contamination of the wound or of the discharges and in excluding the air from the pneumothorax. A fistulous communication with a bronchus is the usual termination of an empyema if left undrained. This spontaneous escape of pus is seldom rapidly achieved. It is rare to find expectoration of pus from an empyema cavity before the eighth week, and the interval is usually much longer. Irrigation is of service in disinfecting the cavity and in preventing the formation of adhesions with localization of the pus. With sufficiently free outlet and with unirritating solutions it is without ill effect. Accidents formerly described appear to have been due to the use of strong antiseptic solutions or to too great pressure.

Treatment of Acute Empyema in Children.—Empyema of the pleural cavity, Souttar says, is a disease common from the second to the sixth year of life, with a mortality very high at first but diminishing with the age of the patient. There are two principal forms — the pneumococcal, often localized by adhesions, and the streptococcal, complete and nonadherent. The latter has a very high mortality, and it is well to temporize by means of aspiration in the acute stage. The former is less fatal, and responds well at a suitable stage to open operation and closed drainage. But if pneumonia is present no such operation must be undertaken until it has subsided, and it is always well to remember that it is the complications of empyema, and not the condition itself, which are fatal.

Empyema in Children.—Romanis says that it is in children that the three rare special varieties of empyema—the apical, interlobar and bilateral forms—are most commonly seen. The chief interest and importance of the apical form lies in its diagnosis—its treatment is not different from that of the other forms of empyema except that its localization must be remembered and the greatest care taken not to disturb or infect the intact pleural space. The interlobar form is also difficult to diagnose, and with regard to the treatment it must be remembered that the condition is practically a localized abscess in the lung; that there is no question of exploring the pleural space; in fact, this latter structure must studiously be avoided. One of the difficulties in these cases will be to find the pus if it is a small collection; the operation should, therefore, always be commenced by inserting a needle into the collection of pus, and this is left in situ while the chest is opened. There is no need to employ one of the closed methods of drainage when dealing with a localized collection of this kind, and an ordinary open drainage tube may be used. In the case of a bilateral empyema aspiration must be tried first, on both sides if necessary. If this procedure gives no relief, that empyema which appears to be the biggest should be drained, while aspiration is continued at intervals on the other side. Finally, after an interval of some days, a simple drainage may be performed on the second side.

Treatment of Empyema.—Higgins stresses the after-care of these cases as being most important, especially breathing exercises to promote reexpansion of the lung on the affected side, after the first two or three acute days are over. The child is encouraged to breathe deeply or to blow out Woulf's bottles while lying on the side of the healthy lung, or with the chest wall on the healthy side compressed by the nurse's hand, or even strapped.

Gastric Secretion After Meal.—From the results of his examinations on 115 healthy persons, Nakao says that the fasting stomach in the early morning is not entirely empty. The quantity of the fasting contents is 41.87 c.c. on an average, mostly between 20 and 50 c.c. The reaction was acid. The average peptic activity is 2.30 mm. In seven cases out of ninety-one no trace of pepsin was found. In 60.9 per cent. of cases examined the stomach contents were colored more or less by the admixture of bile. Mucus was found occasionally, though in a small quantity. Food fragments were found microscopically. The peptic activity of the fasting contents is stronger than that of the gastric juice withdrawn after a test meal.

Blood and Tissue Changes in Cancer.—By means of serum reactions or blood tests, Shaw-MacKenzie has been able, without any clinical knowledge of a case, to differentiate cancer from noncancerous lesions in the majority of cases and, what is hardly less important, in obscure cases and after operation to exclude the presence of cancer. Up to the present, in a total of 261 serums examined (including cancerous, noncancerous and normal), the method has proved correct in 248, or 95.3 per cent. The errors have been associated chiefly with tuberculous, sarcomatous and febrile conditions. In one case (obscure abdominal) the reaction was "negative," but two months later, on postmortem and microscopic evidence, a primary carcinoma of the liver was found. So far, twelve cases of cancer of the stomach have been successfully differentiated from five cases of gastric ulcer, the diagnosis having been verified later. In one case, among others, the serum reactions were found to be quite normal in a patient nine years after removal of her breast for scirrhus. On the other hand, it has been possible to decide as to the latency of the disease after operation. In two cases Shaw-MacKenzie found the "positive" reaction present twelve and eighteen months, respectively, after previous removal of the breast for scirrhus. The patients looked well and were apparently in good health, but within three months of that finding metastasis was only too evident in each case. In another case the reaction was present previous to a small local recurrence after operation for squamous epithelioma of the skin, some twelve months before. These cases show that as long as the reaction persists, the patient cannot be considered free of the disease. It is not claimed that the reaction is specific. There is 5 per cent. margin of error, but the practical utility of the reaction is not greatly affected and is evident in 95 per cent. proving correct.

Fracture Dislocations of Upper End of Humerus. E. W. H. Groves. —p. 513.

Chronic Meningitis Lasting Fifteen Years.—Williams suggests that there are more cases of intractable headache due to chronic germ infection of the meninges than is recognized. She reports one case, that of a woman, aged 55. Horsley diagnosed a meningitis fifteen years ago, but considered it inoperable. The oculist diagnosed "typical migraine," and found bitemporal limitation of fields of vision; fundus normal. These attacks at first occurred every six weeks, but gradually became more frequent. As the years passed, the patient lost strength, and any considerable fatigue brought on an attack. After an attack—not during—there was marked pallor of the face. Insomnia became very troublesome, whole nights being passed without sleep. There were also terrifying dreams. The patient continued to do brain work, and did not consider that this tended to bring on an attack. But it was necessary to work in a warm room (70 F. for choice) and backing the light. Work which required lateral movements of the eyes—e. g., checking a catalog—brought on pain. On waking in the morning, and sometimes during the night, there were jerky movements of arms, hands, legs and feet. When the patient first drank in the morning there was sometimes acute pain at a special point which appeared to be about the cardiac orifice of the stomach, and the patient could not swallow until it passed. After the attacks had continued during some five years it was noticed that before an attack there was frequently slight epistaxis, and during the attack there was constipation. Two unusually severe attacks made it evident that, if operation was not possible, the patient's life would be short. Sufficient bone was therefore removed from the right occipital and parietal regions to allow for access to the cranial contents. Considerable fluid was found outside of the dura mater, with great bulging of the meninges, the dura being under high pressure. The meninges were from three to four times as thick as normal, and this area was removed. The cerebrospinal fluid escaped under high pressure. No sign of tuberculoma was found. The scalp was replaced, leaving a large area without bone. Since the operation the patient is much improved.

Bacteriology of Acute Ileocolitis in Children.—In a bacteriologic examination made by Cruickshank of the stools of twelve cases of acute ileocolitis, *B. dysenteriae* of Flexner-Y type was isolated in seven cases. In the convalescent stage of the illness, atypical dysentery bacilli were isolated from the feces of four patients, and *B. Morgan* I from the feces of the other four. Since *B. dysenteriae* (Flexner) had previously been isolated from the stools of some of these cases, these types were regarded as concomitant bacilli rather than as the causal organisms. There is no conclusive evidence that organisms other than those of the *B. dysenteriae* group are primary infective agents in producing acute ileocolitis, although they may act as secondary factors in prolonging the diarrhea. *B. dysenteriae*, on the other hand, seems to produce an inflammatory condition of the large intestine and the lower part of the ileum, resulting in a type of diarrhea which is clinically distinguishable from acute infective gastro-enteritis. The treatment suggested for acute ileocolitis in children is magnesium sulphate in repeated small doses every morning, together with antidysentery serum as a routine to combat the toxic symptoms.

Mode of Inheritance of Hereditary Ataxia.—Brain asserts that the mode of inheritance of hereditary ataxia cannot be explained on the assumption that the disease behaves as a single mendelian character, whether dominant or recessive. It can be explained satisfactorily if it be assumed that the disease depends on the presence of two mendelian characters, one of which is a dominant and the other a recessive. The percentage of affected offspring expected on this hypothesis is consistent with that actually found.

Heredity in Polycystic Kidney Disease.—In one family studied by Cairns, eight, and probably ten, cases of polycystic kidney disease have occurred in three successive generations, comprising forty-two individuals. The fourth generation does not yet manifest any symptoms of the disease.

*Resistance of Civilized Man to Tuberculosis: Is It Racial or Individual in Origin? L. Cobbett.—p. 577.

Nature of Resistance to Tuberculosis.—Cobbett concludes his review by stating that racial resistance and racial susceptibility are real, and due to hereditary factors deeply fixed in the blood of each race. Superimposed, so to speak, on this high or low resisting power, in every place where the people find themselves brought into contact with tubercle bacilli, there occurs an immunization of the individual. This contact is not without risk, and it is no doubt largely a matter of luck whether the individual meets at first with large doses which produce progressive and fatal tuberculosis, or with small ones which immunize. Doubtless, too, there are doses of bacilli which are safe for a member of one of the more resistant races, such as the Jew, and dangerous to one of the more susceptible, such as a negro; and, on the whole, individual immunization plays a larger part in the case of the more resistant than in that of the more susceptible peoples. But both racial resistance and individual immunization play a part in determining the reaction of the people to tuberculosis, and it would be dangerous to disregard either.

Elective Affinity of Viruses for Certain Cells.—Bard comments on the immunity of certain classes of cells to the filtrable viruses; also on the way in which these viruses promote the development and pathogenic action of certain ordinary bacteria, and how these acquire extra virulence by adsorption of the filtrable virus. Some of the filtrable viruses seem to act electively on the body fluids instead of on the cell protoplasm; the fermentations and other changes induced are of a chemical nature, as in the eruptive diseases. He insists that the pathogenesis of all the diseases with specific cellular lesions needs revision. Behind the visible microorganism lurks the filtrable virus which confers the extra virulence on the visible germ. Clinical observation will differentiate the action of the visible germ from that of its borrowed virulence. Both are important in vaccine therapy, and this explains the superiority of autogenous over stock vaccines. It also explains the difference in the efficacy of serotherapy not only in different diseases but with different strains of the germs used in making the serum. In prophylaxis of disease from the filtrable viruses, isolation is the main reliance. The ordinary "passe-partout" prophylactic measures allow the virus to escape, or impose needlessly severe measures.

Edemas.—Labbé and Violle reiterate that edema never has a single cause, but the multiple causes all induce a single phenomenon, the exaggeration of the capacity of the plasma to absorb fluid. Any or all of the multiple causes may be associated, and this must be heeded in treatment. The primordial derangement may be an upset in the osmotic balance, in the acid-base balance, in the balance between the minerals in the blood, or between the fats and colloids in the blood. With edema from circulatory disturbances, there are more than mechanical factors involved. In edema of nervous origin, vasomotor modifications of the capillary circulation are evident; even in Quincke's edema, a vasomotor link connects the anaphylactic toxic phenomena with the edema.

Rheumatism of the Heart. P. Nobécourt and E. Pichon.—p. 493.
Puncture of the Ventricle in Meningitis. J. Comby.—p. 508.

Serotherapy of Cerebrospinal Meningitis in Infants.—Mogilnicki observed within three years eighty-five cases of cerebrospinal meningitis in infants, eleven in children of from 1 to 2 years, and twenty-one in older children. While in the latter the fever is high and continuous, in infants it is lower and irregular. The chief symptoms of the disease in infants are bulging of the fontanel even when the baby is quiet, also hyperexcitability, manifested in excessive sensitiveness of the skin. The diagnosis should be confirmed by lumbar puncture. He used daily intraspinal injections of 10 to 30 c.c. of polyvalent serum (before the causal bacillus could be detected) combined with intramuscular or intravenous injections of 10 c.c. of the serum. From three to six injections induced complete recovery in only a few cases; in most the treatment was prolonged for two or three weeks. In cases with blocking of the cerebrospinal fluid, the serum was injected into the lateral ventricles. Of eighty-five infants thus treated, twenty-nine recovered, ten improved, forty-six died. A complete cure, without sequelae, occurred in 47 per cent. of the child patients treated the first week of the disease, in 17.6 per cent. treated the second week, and in 11.8 per cent. with serotherapy applied still later. Recurrences of the affection were noted in two cases, cured afterward by renewed injections of the antiserum. Vaccine may be added to the serotherapy in certain cases.

Treatment of Acetonemic Vomiting.—Torello Cendra describes two cases of periodic vomiting from acetonemia in children, aged 6 and under 5, treated with insulin. The acetonuria and the vomiting disappeared from fifteen to twenty-five minutes after a subcutaneous injection of insulin. A carbohydrate meal was given after the injection. The average dose for children of from 4 to 6 years was 10 or 15 units. The effect of the insulin lasted for three hours.

Sterility from Obliteration of the Tubes. E. Douay.—p. 80.

Vaginal Hysterectomy.—Chueco gives nine illustrations showing the advantages and technic of his method of ligating the vessels of the broad ligament and suturing the two sheets of the ligament together, and then suturing the peritoneum behind them. He reproduces illustrations of the Canoc-Marquis method to show the superiority of his technic, as the broad ligaments are left in their normal place.

Acute Peritonitis of Adnexa Origin.—The woman had been sent to the hospital with the diagnosis of acute appendicitis, but the appendix was found sound at the laparotomy. The fever continued and typhoid was suspected, but panhysterectomy finally confirmed the diagnosis of tuberculous processes in both adnexa. These peritonitis cases of adnexa origin are distinguished by the good general condition and pulse. The appetite is often retained, the tongue moist and pink. The more or less hard masses palpated in the depths of the general doughiness may be only slightly tender. There is a marked tendency to formation of adhesions, and the tuberculous lesions invade the viscera by way of these bridges. The acute peritonitis does not yield to ice and other medical measures The fever may persist for weeks and the general health declines. The tuberculous lesion in the adnexa may develop with little if any involvement of the peritoneum. Still another form may simulate gonococcal adnexitis by its stormy exacerbation or its connection with the honeymoon or a confinement. In a virgin, tuberculosis should be suspected; in others the uterus is usually more movable than with gonococcal adnexitis, and the culdesac are less tender and doughy. Ricard and Comte summarize nine cases to show the different clinical pictures that may be presented, and they insist that tuberculous adnexitis is much more frequent than realized. In Tixier's service it formed 25 per cent. of the total chronic salpingitis cases in one year. Simple exposure to the air often cures tuberculous peritonitis, and the outlook is very promising when the focus in the adnexa is removed.

Case of Tuberculosis of Left Kidney; Double Ureter of Right Kidney. H. Blanc.—p. 47.

A Calculus in the Ureter.—Sacchi remarks that a stone in the ureter may long escape detection although causing constant disturbances. They are liable to be ascribed to everything but the right cause. The calculus may persist in the ureter for years without causing local or general disturbances, or it may be responsible for constant pain. The diagnosis may require radiography, an opaque catheter and pyelography.

Reflex Anuria After Nephrectomy.—Nicolich cured the man by decapsulation of the remaining kidney the third day after the nephrectomy.

Syndrome of Fibrinuria.—Imbert treated a man suffering for months with painful attacks of pollakiuria. The pain, persisting several hours, disappeared as soon as what looked like the boiled white of an egg was expelled with the urine. After the urine had stood for a few minutes, it coagulated so that the glass could be inverted without a drop running out. The urine was limpid for several hours; then a white retracted clot appeared at the bottom of the glass. The clot was formed of fibrin. The reaction of the urine was never alkaline; the amount of albumin reached 1.2 per cent. on the day of the attacks; it was absent in the intervals. Neither red corpuscles nor parasites were detected in the urine. The patient seemed otherwise normal. The phenomenon was noted also in a syphilitic man, aged 72. Cystoscopic examination in this case revealed white clots in the bladder, testifying to coagulation of the urine. The clots contained fibrin with leukocytes. Evidently fibrinuria is merely a special form of albuminuria, probably connected with some kidney lesion. The differentiation from inflammations with fibrinous exudate is based on the coagulation of the urine in vitro.

The "Haff Disease." J. Mouzon.—p. 1144.

Glucose Regulation in the Obese.—Labbé and Boulin reiterate that obesity is always connected with a disturbed glucose regulation, revealed by carbohydrate tolerance tests. In certain obese subjects, ingestion of carbohydrate provokes only a more pronounced and durable hyperglycemia than it does in normal subjects. In others, ingestion of 50 gm. of glucose causes hyperglycemia with glucosuria, a paradiabetic condition. The disturbances of glucose regulation with obesity are usually rapidly cured, contrary to what occurs in veritable diabetes.

Lymphocytosis in Relapsing Fever.—Analysis of the blood in eighty cases of recurrent fever showed Karwacki that lymphocytosis constantly preceded by two or three days the appearance of a febrile relapse. This occurred even when no spirochetes could be discovered in the blood. The examination of the blood should be repeated, since lymphocytosis may reappear in from eight to thirty days. No case of relapsing fever can be considered as cured before that time. In 56 per cent. of the patients, not treated with neoarsphenamin, the leukocyte count was normal by the second week of convalescence; in 44 per cent. by the third week. In 43 per cent. of the treated, the leukocyte count was normal the second week; in 28 per cent. the third week; in 21.5 per cent. the fourth week, and in 7 per cent. the fifth.

Complement Fixation in Genital and Urinary Tuberculosis.—Among fifty-one patients with renal tuberculosis the fixation of complement was positive in 90 per cent. and in 12 per cent. of the cases of kidney disease of nontuberculous nature. Thirty-six cases of tuberculous orchitis and epididymitis, with or without lesions of the bladder and prostate, showed a positive reaction in 68 per cent. In fourteen cases of nontuberculous genital affections, the reaction was always negative. Complement fixation may evidently be of great help in cases with uncertain diagnosis.

Anastomosis of Gallbladder with Stomach. Villard and Richer.—p. 455.
*Remote Results of Periarterial Sympathectomy. P. Mornard.—p. 467.

Early Differential Diagnosis of Gallstone in Bile Duct.—Leveuf and Berceanu reiterate that, even with roentgenography, the duodenal tube and the usual examination of the blood and urine, calculi in the common bile duct may escape detection till jaundice occurs. They endorse Delbet's method which proved helpful in their cases. As soon as a painful attack appears, suggesting a gallstone in the bile duct, the urine should be examined every two hours. To 10 c.c. of urine, 1 c.c. of 10 per cent. barium chlorid solution is added. This is mixed with 1 c.c. of alcohol (95) and 1 drop of hydrochloric acid; then left in the water-bath for one minute. A green tint indicates the presence of bile pigments. In the twenty-four hours urine the pigments may be so diluted as not to show, but they appear if the urine is examined every two hours. They are usually found from the fourth to the sixth hour following the attack of colic. The findings with this method were always confirmed by the operation.

Remote Results of Periarterial Sympathectomy.—Mornard applied Leriche's periarterial sympathectomy in fifteen cases. Immediate results were noted only in four cases of leg ulcer from varices or phlebitis; also in a case of trophic ulcer. The healing was more rapid than with other treatments. But the cure did not persist; the lesion reappeared after from one to three months. The operation was without any effect in the gastric crises of tabes and in cases of gangrene.

Surgical Treatment of "Essential" Incontinence of Urine.—Operations were made by Delbet and Leri on twenty-four patients with enuresis; in twenty cases the roentgen ray showed spina bifida. Operation revealed in every case a fibrous band bridging the gap and compressing the dural culdesac and the nerves of the cauda equina, affecting chiefly the sensory fibers. This yellow band ligament was found not only in the lumbar region but also in the sacral, evidently due to defective union of the sacral vertebrae or to the persistence of the ligament in apparently united vertebrae. The operation consisted in resection of this band. There were one and sometimes several of these bands. Ten patients were cured; ten were only slightly improved; in three the results were negative. They regard this band as responsible for the enuresis. All with purely nocturnal enuresis were cured. The failures were all in patients with chronic nervous or mental disease or a history of some urogenital disease. The scar of the operation is liable to induce recurrence by its pressure.

*Blood Grouping in Twins. A. F. Canelli.—p. 385.
*Virus of Acute Poliomyelitis. A. Pagani Cesa.—p. 397.
*Influence of Baths on Child Organism. A. Lorusso.—p. 405.
*Action of Cholesterol. G. Halfer.—p. 425.

Blood Grouping in Twins.—Canelli examined thirty-nine sets of twins from 8 days to 6 years old, and found that both of the univitelline twins were invariably of the same blood group. Four of the nonidentical twins were of different groups, including two of different sex. The majority of the twins were of Groups I and II of the Jansky classification.

Virus of Acute Poliomyelitis.—Pagani Cesa states that with the Di Cristina culture medium he succeeded in cultivating the virus from the lumbar puncture fluid during the febrile stage in six infants with acute anterior poliomyelitis. The virus could be transplanted in series directly or after filtration through the Chamberland or Berkefeld. When the slide was left in Löffler's solution for ten to twelve hours, the germs could be seen with the microscope. In two other young children at the eighteenth and twenty-second day the findings were negative.

Influence of Hot and Tepid Baths, Air Baths and Sun Baths on Child Organism.—Lorusso's tabulated data confirm that the modification of heat regulation and increase of insensible perspiration during air baths justify their use as a tonic measure to strengthen the general health.

Action of Cholesterol.—Halfer began with 0.20 gm. of cholesterol by the mouth, giving it daily to ten children convalescing from pneumonia or rickets or with congenital syphilis. Doses of 2 or 3 gm. were never surpassed. The number of erythrocytes increased regularly and permanently, and the blood corpuscles became more resistant. No toxic by-effects were observed in any instance, and Halfer thinks we can regard cholesterol as a useful adjuvant in treatment of anemia.

Some Necropsy Findings in Pleuritis. Sindoni and Guccione.—p. 893.
The Modern Conception of Scrofula. O. Cozzolino.—p. 902.

Psychology of the Sick Child.—Borrino insists that the physician should examine the mental and emotional development as well as the physical in young children with chronic disease. Only in this way can we obtain standards and data to guide in warding off abnormal conditions later. She outlines the method of examination she has found most instructive.

Cholera Infantum.—Canelli was surprised to find blood in the stools and vomit and often in the urine of 100 young infants with choleriform diarrhea. There was no biliverdin in the stools in the majority, but in the grave cases the excess of uric acid in the urine paralleled the progress of the toxic syndrome. Acetone and indican were frequently present in the urine, and both stools and urine gave a strong reaction for acid, but there was no glycuronuria. The blood and the nerve tissue were toxic for guinea-pigs. He defines the disease as a gastro-enteritis with degenerative and inflammatory lesions in organs, parenchymatous hemorrhages and gastro-intestinal hemosiderosis and hemorrhage. The other type of gastro-enteritis in young infants does not have the degenerative lesions nor parenchymatous hemorrhages, but there may be gastro-intestinal hemorrhages.

Diabetes in Children.—Pollitzer reports two cases, in boys of 6 and 14. The carbohydrate metabolism was extremely unstable, the hypoglycemia in the half hour after insulin was intense, as also alimentary and epinephrin hyperglycemia.

Excellent Ultimate Results of Phrenicotomy in Pulmonary Tuberculosis. E. Curti.—p. 1180.
Spa Treatment of Cholelithiasis. G. Sabatini.—p. 1181.

Intradermal Test for Hydatid Disease.—Sette presents evidence that the fluid of a hydatid cyst can be filtered through porcelain and heated to 70 C. without losing its specific power to induce a typical reaction when injected intradermally in a subject infested with the echinococcus. He evaporates 150 c.c. of hydatid cyst fluid and mixes the residue with 10 c.c. of 0.9 per cent. sodium chlorid solution and 20 c.c. of glycerol; 0.1 c.c. of this fluid is used for the Casoni intradermal and subcutaneous tests. Both this extract and the filtrate proved durable, up to a year in his experience. Even with twice the amount he was unable to elicit a positive response in forty-six controls.

*The Spleen in Hemorrhagic Disease. Prospero Mino.—p. 365.
*Mesenteric Lymphogranulomatosis. Giovanni Antonelli.—p. 391.
Primary Cancer in the Thymus of a Man. G. Cortese.—p. 417.

The Spleen in Hemorrhagic Maladies.—Mino's observation and research have convinced him that the theory of some special activity of the spleen in these conditions has only an apparently solid base. The same modifications of the platelets, leukocytes and bone marrow, obtained by irradiation of the spleen, can be realized by exposure of distant regions (ear). The resisting power of the vessels can be modified by irradiation of the ovary as well as of the spleen. Only in constitutional, hereditary idiopathic purpura, the effect of splenectomy reveals that this organ has evidently some influence on the still unknown pathogenic elements. He says that in symptomatic purpura, splenectomy has never given positive results, and seven deaths are recorded in forty splenectomies in cases with a rapid onset and acute course. He adds that a diminished number of blood platelets is no criterion for the differential diagnosis.

Lymphogranulomatosis.—In Antonelli's patient the mesenteric glands were almost exclusively involved, and the disease ran only a five months' course. The structure was of the blastoma type.

*Dispensaries for Congenital Syphilis. Ivan Prieto N.—p. 263.
*Destruction of Hospitals by the Earthquake. O. Oyaneder.—p. 278.

Policlinics for Congenital Syphilis.—Prieto discusses the disadvantages of the present system of caring for children with congenital syphilis, and outlines a plan for concerted action and mutual cooperation by dispensaries making a specialty of thorough treatment of congenital syphilis, with visiting nurses and carefully kept charts.

Reconstruction of the Chile Hospitals Destroyed by the Last Earthquake.—Oyaneder describes how the work of the hospital went on although all the older portions had been entirely destroyed. The Copiapó hospital had only the maternity, the children's ward and the kitchen left. A temporary Red Cross structure had to be used for the Vallenar hospital, which had been totally destroyed. The reconstruction has been on an elaborate plan. Only the women's pavilion, kitchen and laundry have been completed as yet. Funds for reconstruction of this hospital were collected by women's organizations in Argentina.

*Oxalic Acid Poisoning. W. E. Coutts.—p. 1118.
Case of Senile Dementia with Melancholia and Delirium. Camauer. —p. 1122.

Sclerosis of the Pulmonary Artery.—Arrillaga gives thirteen plates showing the clinical and microscopic aspect of Ayerza's disease. He regards it as a primary affection, of syphilitic origin, while Ayerza assumes that it is secondary to some chronic pulmonary lesion. The hypertrophy of the right ventricle and the histologic lesions and enlargement of the pulmonary artery entail the extreme cyanosis of these "black cardiacs," the dyspnea, polycythemia, hemoptysis and angina pectoris. Oblique roentgen examination is most instructive.

The T Wave in the Electrocardiograph.—Bosco reiterates that in heart disease the negative T wave in Leads I and II justifies a grave prognosis. With its persistence in spite of treatment, the patient will die within a year. In a single derivation, and in Lead III exclusively, the negative T wave has no diagnostic import.

Vulvovaginitis in Little Girls.—Castilla found evidences of inflammation and ulceration regularly in vulvovaginitis of 100 little girls. The inflammatory process usually involved the cervix. He regards these findings as indicating treatment with surgical solution of chlorinated soda. He instils once or twice a day, 5-8 c.c. of a 1 or 2 per cent. solution in olive oil, the pelvis raised. The fluid is retained for five or ten minutes and is then allowed to escape. Improvement was prompt in the ten cases in which this treatment was applied, and one was permanently cured; some of the others required renewed treatment later.

Oxalic Acid Poisoning.—In the two cases described, about 10 or 20 gm. of oxalic acid had been ingested. Treatment was with infusion of an isotonic or hypertonic solution of glucose, as retention of urea seems to be the principal disturbance. Coutts ascribes to this the cramps, and convulsions often observed in such cases. Pains and muscular stiffening in the epigastrium were the only symptoms in one of his; in the other there was a burning sensation and vomiting until after lavage of the stomach, but the urine was free from cells, and both recovered promptly and completely.

*Congenital Generalized Edema. J. Bazán et al.—p. 101.

Instrument for Suturing in the Depths of Cavities.—Samengo's instrument combines a needle holder, suture material holder and forceps. There is also an extra blade between the other blades to supply the plane of resistance for the tissues as the needle is drawn through the opening at the tip of this extra blade. The "Suturador" is especially designed for ear and throat work. It allows all the various steps of the operation to be done rapidly in the depths, with the sole exception of tying the knot. Fourteen illustrations accompany the description.

Roentgenologic Study of the Circulatory Apparatus.—The roentgen-ray findings with the heart and aorta are discussed, with fifty-three illustrations. The article supplements Viton's similar study of the respiratory apparatus in a preceding number.

Congenital Generalized Edema.—The child was born prematurely and presented universal and extreme edema. The mother had had acute nephritis following diphtheria three years before, and there had been a tendency to edema during the pregnancy. The child died without having cried. Bazán adds that there are only about eighty cases of congenital universal edema on record.

Renal Insufficiency in Circulatory Disturbances in Childhood.—Renal disturbances due to chronic stasis are rare in children. Eckstein reports in detail such a case. The patient, who had a severe endocarditis and who developed *cor bovinum*, was observed from the age of 3½ years to his death at 8¾ years. The earliest renal symptom was a decrease in water output. Albumin was found in the urine in various amounts and up to as much as 1.8 per cent. The albuminuria decreased whenever the function of the heart was poorer, and at the same time the protein content of the ascitic fluid increased. The urine sediment did not show any parallelism with the albuminuria; leukocytes, erythrocytes and casts made their appearance at various times. The necropsy showed that the kidneys were not increased in size; the renal capillaries were strongly congested, but no formation of connective tissue was found. That a chronic passive hyperemia of five years' standing did not induce the development of interstitial connective tissue, may explain why the true contracted kidney is so rarely found in children.

Vomiting in the First Days of Life.—Lust reports three cases of new-born infants, who vomited violently, beginning with the first intake of food. The condition lasted only a few days, and he believes that it was caused by muscular spasms of the stomach.

Endocrine Glands and Intestinal Tract. F. Boenheim.—p. 337. Conc'n.

Cell Membranes and Fermentation of Feces.—If fine cell membranes are added to not fermenting feces, fermentation will begin within twenty-four hours. The same is true if these cell membranes are added to the food. Weiss concludes that all vegetables, even those which do not contain any starch, should be excluded from the diet for patients with fermentative dyspepsia.

Influence of Cold Applications on the Stomach.—The application of an icebag on the stomach does not in any way influence the shape, the tonicity, the motility and the pyloric mechanism of the stomach. The peristalsis, however, is increased after half a minute to a minute and a half. Since the same effect is obtained when the cold application is applied to any other area of the skin, Friedrich and Bokor conclude that the effect of a cold application must be due to a reflex mechanism

Immunologic Results After Symptom-Free Infections with Spirochetes.—It is possible in various ways to infect mice with the spirochete of relapsing fever without causing a bacteremia or any symptoms of disease. Reiter has coined the term *stumme Infektion* for this condition These mice are immune against infections which prove to be lethal in control animals. Injection of killed spirochetes has not the same immunizing effect. This immunity can be transferred with the brain but not with the serum

Rat-Bite Fever.—Gussew reports a typical case of this disease which is interesting in so far as there are no previous cases on record from Lithuania or the neighboring countries.

Roentgenologic Visualization of the Gallbladder.—Pribram, Grunenberg and Strauss used the Graham-Cole method of cholecystography on a large number of patients, and report very satisfactory diagnostic results. They believe it advisable to empty the gallbladder before the injection of the tetrabromphenolphthalein, and found that the injection of pituitary extracts answers this requirement perfectly In order to prevent the disagreeable ill effects which the injection of the dye causes in some patients, they gave atropin prophylactically with good results

"Antiphagin."—After injection of bacteriophage culture into experimental animals, their serum displays an inhibiting action on the bacteriophage used for the injections Sonnenschein did not witness "antiphagin" action in the serum of 100 patients with various diseases But in two paratyphoid patients he found an "antiphagin" against a paratyphoid bacteriophage.

Retinal Hemorrhages in the New-Born.—On the strength of experimental observations, Metzger emphasizes the importance of a negative pressure on the skull during delivery *for the genesis of retinal hemorrhages.*

Experimental Dehydration and Liver Glycogen.—Young dogs were kept on a diet consisting of desiccated milk, and very little water. These animals developed grave general disturbances and losses in weight The refraction of their serum increased (dehydration of the blood), and the glycogen content of the liver was markedly reduced; fatty changes occurred if the diet was kept up long enough. The addition of sugar to this diet hastened the pathologic changes mentioned above. In dogs kept on a diet deficient in water but free of proteins, no pathologic changes occurred Schiff, Bayer and Choremis conclude that the decrease of the liver glycogen is not caused by the dehydration but by toxic protein intermediary products.

Complement and Cholesterol Content of the Serum in Scarlet Fever.—Szirmai found that the cholesterol is usually decreased, but that the complement is not reduced, which is an argument against the theory that scarlet fever is an anaphylactic condition.

Improved Micromethods.—Holtz announces a new system of gravimetric methods for physiologic chemistry, which works with much smaller amounts of material than usually employed and with no less degree of accuracy. In this first report he explains the construction and handling of a scale which allows of an accuracy of 0.0001 mg

The Normal Bilirubin Content of the Blood.—Forster describes a colorimetric method for the determination of the bilirubin in blood. He records the findings in *234* cases, including sixty-three normal controls Under normal conditions the bilirubin may range from 0.2 mg. to 1.0 mg. per hundred cubic centimeters of blood serum

Sleep and Sleep Center.—Reviewing the various theories on the mechanism of sleep, and analyzing clinical observations on disturbances of sleep, especially the clinical and pathologic material from patients with encephalitis lethargica, Haenel arrives at the conclusion that sleep must be centrally regulated The proper function of this regulation is dependent on the anatomic integrity of a certain part of the brain, *in the mesencephalon.*

Ions, Hormones and Vegetative Nervous System.—Kylin has demonstrated by clinical experiments that calcium ions, epinephrin and the sympathetic nervous system are antagonistic in their function to potassium ions, insulin and the pneumogastric nerve. Calcium ions, for example, have a depressing effect on the insulin action on blood sugar; potassium ions enhance this effect.

Functional Liver Tests.—Glycosuria after the ingestion of dextrose is not a reliable indicator for the functional efficiency of the liver. A test, the findings of which correspond much more closely with the clinical and pathologic findings, is to determine the blood sugar curve after the ingestion of galactose. This curve is much modified in all parenchymatous changes in the liver. Jaundice caused by diffuse inflammatory conditions, gives a positive response; jaundice caused by localized processes (tumors, for example) has a normal curve. In cirrhosis of the liver the hyperglycemia is of much increased duration, although there may be but little glycosuria. Kähler reports the results of the test on thirty-six patients, and declares that this galactose test is much superior to the dextrose test.

Roentgen-Ray Treatment of Axillary Sweat Gland Abscesses.—Rütz, who has treated about sixty patients with a combination of incision and roentgen-ray irradiation, believes that this combined procedure is the method of choice. He found histologically that the roentgen-ray treatment stimulates the formation of connective tissue; the sweat glands are structurally not altered, but their function is apparently lost.

Hematologic Differentiation Between Tuberculous and Purulent Meningitis.—In purulent meningitis many pathologic leukocytes and a shifting towards the left are found; there are only few monocytes. In tuberculous meningitis no pathologic leukocytes are present, and no shifting of the white cells, and the monocytes are increased in numbers. Heissen believes that these findings allow of a differential diagnosis.

The Hygiene of Clothing.—Friedberger makes a fervent plea for more hygienic conditions in our clothing, especially in summer clothing for men. He believes that the recent fashions in women's dress should lead men's fashions to more rational garments.

Vagotonic and Sympathicotonic Symptoms.—Ganter scrutinizes the Eppinger and Hess theory and comes to the conclusion that the diagnosis of sympathicotonic and vagotonic conditions is far too readily made. Since it is not possible to demonstrate the tonicity of the one or other system directly, but only by their effects on the organs in which they end, the special condition of a particular organ may simulate an increased or decreased tonus of the nervous system. The pharmacodynamic reactions which are widely used in this connection are unreliable. Certain symptoms, such as bradycardia, constipation, eosinophilia, which are generally referred to functional conditions of the vegetative nervous system, have never been proven to be of nervous origin.

Glucose Test of Liver Function.—In this preliminary communication Arnoldi describes the findings in 300 subjects after ingestion of 20 gm. of glucose—his new carbohydrate functional test of the liver. The bilirubin content of the blood serum rises, and the conditions of this rise seem to vary characteristically with different pathologic conditions.

Spirochetes in Pernicious Anemia.—Determann believes that the corpuscular elements, which Meessen described lately as spirochetes in the blood of patients with pernicious anemia, are broken up red cells, or hemoconia according to Türk. Determann found the same elements frequently in the blood of normal persons.

Colloid Chemistry and Homeopathy.—Traube enters into the rather violent discussion about homeopathy, which was started recently by Bier, and enumerates a large number of facts from his colloid chemistry studies to show how extremely small quantities of certain substances may exert very considerable effects, and that, indeed, small quantities of the same material may have the opposite effect to large quantities.

Syphilis and Frambesia.—Jahnel and Lange tried to infect with the frambesia spirochetes four persons with general paresis, but the patients proved to be immune against this virus, very likely on account of the close biologic relation which exists between the spirochete of syphilis and that of frambesia.

Transformation of Exophthalmic Goiter into Myxedema.—Curschmann reports the case of a woman, aged 41, who developed acute but mild exophthalmic goiter. After careful roentgen-ray treatment she developed a moderately severe myxedematous condition.

*The Clinical Aspect of Typhus. M. M. Gubergritz.—p. 159.
*Viscosity of the Serum in Joint Disease. Kauftheil and Simó.—p. 191.

Acute Leukemia.—Dimmel reports in detail two cases with the necropsy findings. He believes that acute leukemia is not an infectious disease. The histologic changes are very similar to those found in chronic leukemia, and the predominating hematologic features are the quite immature and degenerated cells.

The Clinical Aspect of Typhus.—The incubation period seems to be five to twelve days. Rather characteristic is a drop in temperature on the second day (sometimes the third or fourth day) after the onset of the fever, which is followed by a high rise. After about fourteen days the temperature returns to normal within two days. Arrhythmias of the pulse and low blood pressure are observed in most of the cases. The physical signs and the clinical significance of the circulatory disturbances are thoroughly discussed. Bronchopneumonia is frequent. Various disturbances of the intestines and the urinary system are observed. Women frequently menstruate at the onset of the disease, but abortion is very rare. A leukopenia is usually found in the beginning, which at the end of the first, or the beginning of the second week is followed by a mild leukocytosis. Gubergritz bases his report on observations of more than 200 patients, which he saw during the recent epidemics in Russia.

The Specific Viscosity of the Blood Serum in Joint Diseases.—Kauftheil and Simó found that the specific viscosity of the serum is .96 to .99 in normal persons, and that it is increased in joint disease parallel to the amount of tissue waste and the severity of the inflammatory processes.

Wilhelm Roux and His Work. G. Pommer.—p. 963. Cont'd.
Treatment of Vocal Disturbances. E. Fröschels.—p. 967.

Mechanism of the Vesicular Breathing Sound.—Winkler believes that his experimental observations prove that the vesicular breathing sound does not originate in the alveoli but in the peripheral ramifications of the bronchi.

Sclerodermia in Infants.—Dolinšek and Ermenc report two cases of this disease with a very benign course. They believe that this disease is not identical with the one observed in older children, and they advocate Mayerhofer's term "benign, indurative infiltration of the subcutaneous tissue in the new-born."

Varicose Veins and Sunken Arches.—These two conditions are frequently found associated in the same patient, but it is not probable that one is the cause of the other. It appears rather that both conditions develop on the same predisposition, a constitutional weakness of the mesenchymatous tissue in the walls of the veins, in joint capsules and in ligaments; and that habitual influences frequently make the diseases manifest. Nobl and Remenovsky furthermore emphasize the relations which may exist between what they call "the varicose complex" and other acquired bone and joint anomalies.

Studies in Gastric Lipase.—Landsberger found that lipase from the stomach of infants splits tributyrin more quickly in whey of human milk than in that of cow's milk. The inorganic compounds in the whey are not the cause for this difference.

Paratyphoid in Childhood.—Intestinal paratyphoid infections in young children may produce a very mild disease and simulate an ordinary diarrhea. Schmidt emphasizes the epidemiologic importance of diagnosing such cases properly.

Noninfected Children in Tuberculous Families.—Zimmermann reports anew some data which show that a considerable number of children, who are exposed to tuberculosis by coresidence with tuberculous persons, do not contract the disease and do not become sensitive to tuberculin.

Water Balance in Myxedema.—Nobel and Rosenblüth found that in myxedematous children the insensible perspiration is diminished and that the quantity of the feces in relation to the quantity of food is decreased.

Treatment of Myxedema.—Nobel and Rosenblüth publish a table which shows how much thyroid substance, according to the size of the patient, must be given in order to obtain a satisfactory physical and mental development.

Combination of Diabetes Mellitus and Renal Glycosuria.—Vogelenzang reports two cases of this combination and states that he knows of no analogous cases in the literature. The men, aged 47 and 39, had presented symptoms suggesting diabetes for several months up to three years, but the sugar content of the blood was constantly at or below the normal figure. The glycosuria rose and fell with the diet and the glycemia with alimentary tests in the same manner as the glycemia in true diabetes. The only explanation, he says, is a casual combination of true diabetes and renal glycosuri as he insists there can be no transition between two such opposite affections. He adds that the renal factor has a favorable influence on the diabetes. It is certainly a great advantage that the sugar is cast off with such a low glycemia. He does not think that dietetic restrictions are necessary. There is danger, however, of carbohydrate starvation from the excessive losses. Both of his patients had acetonuria, and it increased when carbohydrates were restricted. Galambos has reported a case with 97 to 156 gm. of sugar in the urine to 0.089 per cent. of sugar in the blood, fasting, and death in coma a year later.

Acute Myeloid Leukemia. K. Pelger.—p. 828.
Ontogenetic Recapitulation as a Hormone Phenomenon. L. Bolk.—p. 844.

Treatment of Puerperal Sepsis.—Ten Berge relates that two died of twenty-four women with sepsis, after childbirth or abortion, treated by Luker's method of injection of a polyvalent streptococcus antiserum followed by intravenous injection of quinin. Parallel series treated the same otherwise, *but without the antiserum and quinin, gave identical* results.

Stain Tests of Liver Function.—Peutz prefers the Rosenthal method: estimation of the proportion of the stain retained in the blood serum, instead of the proportion eliminated in the bile. His experiences with 137 cases confirmed that tetrachlorphthalein is eliminated almost exclusively by the bile, but the test throws light on only one function of the liver, namely, the ability to eliminate foreign substances. Azorubin appeared in the bile in less than five minutes in dogs and fifteen minutes in man, but it was eliminated to some extent by the kidneys. This detracts from its value as a liver test.

Cystin Metabolism in Children.—Lignac ascribes a causal import to the deposits of cystin he found in three male infants who had succumbed to progressive atrophy. He reports here a new case. Hydrocephalus had developed with chronic meningitis consecutive to epidemic meningitis in early infancy. The infant (female) died from progressive atrophy at the age of 14 months, and one or two large calculi —composed almost entirely of cystin—were found in each kidney pelvis. The kidneys were extremely pathologic, and there were signs of mild rachitis. On the basis of recent research by himself, Mendel and others, Lignac theorizes to explain the importance of cystin for the oxidative processes. He accepts the retarded growth in these four instances of deranged cystin metabolism as the consequence of the defective assimilation of this indispensable amino-acid.

Relations between Nodular Erythema and Tuberculosis. T. Oldenburg. —p. 577. Conc'n.
*Rays from Cod Liver Oil. H. Haxthausen.—p. 585.

Radiation from Cod Liver Oil.—Haxthausen relates that a photographic plate laid on a Petri dish of cod liver oil shows something resembling photographic action with a four to six hours' exposure. The openings cut in an interposed black paper, and the differences in the action according to the depth of the cod liver oil apparently confirm the reality of the photographing faculty. On the other hand, the action was entirely arrested by a sheet of glass or of quartz, and the electroscope findings were negative. The action may be of the same nature as the "Russel effect" on the photographic plate, the "Moser ray," which is due to diffusion of some chemical substance with possibly some supplementary photographing energy. There seems to be a certain parallelism between the photographic efficiency of the cod liver oil and its curative action in rickets. Linseed oil possesses the faculty to a slight degree but not butter, milk, eggs, olive oil, etc. Vegetable oils acquired it, however, after exposure for an hour to ultraviolet rays. Linseed oil was preeminent in this respect. Mineral oils did not acquire the faculty under any conditions, but galvanized iron wire and wood developed it after irradiation. This is interesting in view of Hume and Smith's statement that irradiation of the glass vessel had no action on experimental rickets unless there was sawdust in the bottom of the glass. The fats in the skin have a similar action on the sensitive plate after ether extraction and irradiation. The action of light on rickets may be due to the effect on the fats in the skin. The research reported confirms, he says, Kugelmass and McQuarrie's conclusions as to the connection between the antirachitic and the photographic action.

*Virulence Tests in Gynecology and Obstetrics. O. K. Svenningsen. —p. 620. Begun, p. 594.

Test for Reaction of Arterial Blood.—Drucker and Cullen describe a method for examining the blood, drawn under paraffin oil, without loss of carbon dioxid.

Pneumococcus Types in Pneumonia.—Christensen declares his experience in 150 cases indicates that the prognosis cannot be based on the type of pneumococcus involved.

Acidosis and Retention of Chlorid in Croupous Pneumonia. —Holten's search for acids in the urine of thirteen pneumonia patients was constantly negative with the exception of lactic acid. The urine contained lactic acid, and he theorizes that this is responsible for the retention of chlorid, the organic acid acting on the tissues, especially on the kidneys.

Virulence Tests in Gynecology and Obstetrics.—Svenningsen regards the Ruge method as a valuable aid in oversight of the course of the infection and thus a guide to treatment.

*Kidney Calculi. J. Hellström.—p. 529.
Anatomic Basis for Vision. S. E. Henschen.—p. 555.

Kidney Calculi.—Hellström emphasizes the necessity for determining the causes for the production of the calculi, their nature, and whether they are in a progressive, stationary or retrogressive stage. He had 128 patients with kidney or ureter calculi in 1911-1922, and 85 per cent. have been reexamined lately. Nephritic colic was present in 68 per cent. and signs of pyelitis in 22 per cent. of the seventy-five men and 50 per cent. of the fifty-three women. In 10 per cent. of ninety-two cases the parents had likewise had nephrolithiasis. In ten, staphylococci seemed to have been the nucleus of the calculus. There was spontaneous passage of the calculi in 38 per cent.; in three cases a large branching calculus was cast off spontaneously. It had developed rapidly during extension treatment of a fracture or under other unusual circumstances. As the patients resumed their daily life, the loosely structured stones yielded to the restored *normal conditions in the urine and disintegrated.*

CANCER MORTALITY IN THE TEN ORIGINAL REGISTRATION STATES

TREND FOR THE PERIOD 1900-1920[*]

J. W. SCHERESCHEWSKY, M.D.
Surgeon, U. S. Public Health Service
BOSTON

The progressive increase in the cancer death rates shown in the mortality statistics in practically all civilized countries has invited the serious attention of students of the public health. The more optimistic are of the opinion that these increases in the death rate may be accounted for by improvements in medical diagnosis, increase in the accuracy of vital statistics in general, greater precision in filling out death returns, changes in the age distribution of the population and similar factors.

Yet others are inclined to a gloomier view of the situation. They hold that the magnitude of the observed increases in the death rate is too great, too general in its distribution to be accounted for in any such way, so that the apparent is also an actual increase in the cancer mortality.

Because of the importance and interest of this question, it was thought well worth while to attempt a critical analysis of the course of the cancer mortality in the ten original registration states; i. e., Connecticut, Indiana, Maine, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Rhode Island and Vermont. This area was chosen because it is the only one available in this country for continuous study over the selected period of twenty-one years, as the other states now forming the registration area were added from time to time to the original ten.

Moreover, these states, with the exception of Indiana and Michigan, were all situated in a similar geographic section. The population, about 19,800,000 in 1900 and more than 27,000,000 in 1920, represents about 25 per cent. of the total population of the United States, and hence is sufficiently large to give considerable mass value to the data. Besides this, the population is about as homogeneous a group as we are likely to get in a country made up of such diverse racial stocks as ours, and it exhibited about the same changes in racial composition, owing to immigration during the period of observation.

The source of the data for analysis was the published mortality statistics of the U. S. Bureau of the Census, and the decennial census reports.

The following method of study and analysis was employed:

Taking the enumerated populations of "all ages," and also for the specific age groups "under 5 years," 5-9, 10-19, 20-29, 30-39, 40-49, 50-59, 60-69, "70 years and over" as given in the U. S. census reports of 1900, 1910, 1920, the intercensal population of all ages and by specific age groups was estimated by the arithmetical method. In estimating the population, compilations were made as of January 1 instead of July 1 because of slightly greater convenience, while at the same time no sensible error in the comparative validity of the tables was introduced. Since specific age groups were dealt with, the population of unknown age was omitted from the estimated figures.

General cancer death rates and specific death rates were then computed, first, for all forms of cancer and then for cancer by the seat of organ affected, the international classification[1] being used. In the case of cancer of the breast and cancer of the female genital organs, rates were computed on the basis of the estimated female population, as cancer of the breast is almost wholly, and cancer of the female genital organs exclusively, confined to that sex.

The extent of death certification by medical men, the changes and improvements in the practice of death certification and in diagnosis, the corrections to be applied for changing age distribution, and finally changes in racial stock due to immigration and the effects of these factors on the mortality rates were each considered in their turn. The results of this analysis and interpretation of the data are now in the process of publication. They are entirely too long to be given in extenso here. However, by using a somewhat different method of age grouping, the main results of the inquiry, their interpretation, and the resulting conclusions may be briefly presented.

The population aged 40 years and over is the important age group, so far as cancer mortality is concerned. In 1900, in the states under consideration, this age group furnished about 89.8 per cent., and in 1920 about 92.5 per cent. of all the cancer deaths.

The population 40 years and over of the ten original registration states was 5,313,459 in 1900; in 1920, 8,145,709. It had the age distribution given in Table 1.

From this age distribution the somewhat unexpected fact is noted that, in spite of the increase in the median age of the general population that has taken place since 1900, in the population aged 40 years and over, the proportion of elderly persons 60 years and over was greater in 1900 than it was in 1920 (29.17 and 28.14 per cent., respectively). If we redistribute the 1920 population of 40 years and over according to the 1900 percentage composition and apply the appropriate 1920 cancer death rates to each of the resulting age groups, it is found that, instead of the 25,368 that were reported for this section of the population, 25,806 deaths would have occurred. This corresponds to a rate of 316.8 per hundred thousand, or 5.4 points higher than the observed 1920 rate of 311.4.

---

[*] Read before the Section on Preventive and Industrial Medicine and Public Health at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

[1] In the international classification of causes of death, cancers are thus divided: The general rubric is: "cancer and other malignant tumors' which, in turn, is subdivided into: (1) cancer of the buccal cavity; (2) cancer of the stomach and liver; (3) cancer of the peritoneum, intestines and rectum; (4) cancer of the female genital organs; (5) cancer of the breast; (6) cancer of the skin; (7) cancer of other organs or of organs not specified. It should be noted that this classification was not quite uniform for the twenty-one years. Thus, prior to 1910 we find the rubrics "cancer of the mouth" and "cancer of the intestines" in the place of "cancer of the buccal cavity" and "cancer of the peritoneum, intestines and rectum." These differences in classification may have had some effect on the figures, though this was probably small.

TABLE 1—*Age Distribution of Ten Original Registration States*

Age Group	1900 Population	1900 Per Cent	1920 Population	1920 Per Cent
40-49	2,228,723	41.94	3,421,204	42.00
50-59	1,534,625	28.88	2,431,692	29.85
60-69	963,991	18.14	1,453,490	17.84
70	586,120	11.03	839,413	10.30
	5,313,459	99.99	8,145,709	99.99

From this it follows that the cancer death rates in this group of the population may be compared for the period of 1900-1920 without the necessity of introducing any correction for a changing age distribution, as any correction for this factor would have the effect of slightly increasing instead of lowering the rates of the later years of the period

Therefore, we arrive immediately at the conclusion that any increases observed in the cancer deaths of this group of the population are independent of changes that may have taken place in the age distribution.

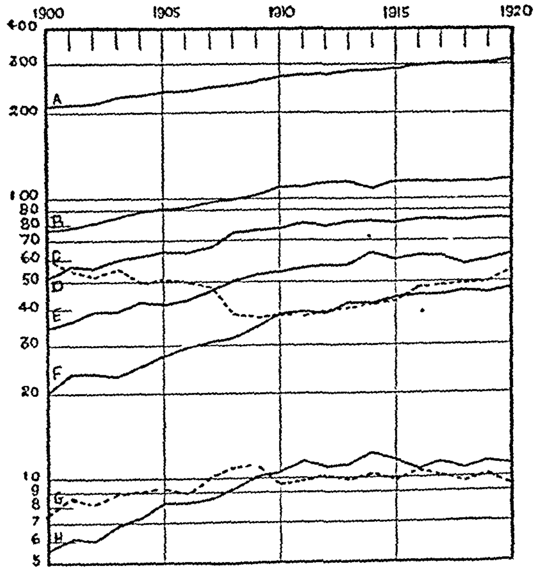

Chart 1—Death rate, per hundred thousand of population, from all forms of cancer and by site of organ affected, in age group 40 years and over, in the registration states of 1900 for the period 1900 1920 *A*, cancer, all forms, *B*, stomach and liver, *C*, other organs or organs not specified, *D*, female genital organs, *E*, female breast; *F*, peritoneum, intestine and rectum, *G*, skin, *H*, buccal cavity.

Chart 1 and Table 2 show the changes that have occurred in the death rates from cancer of all forms, and by site of the organ affected in the population 40 years and over, the rates for cancer of the breast and cancer of the female genital organs being based on the female population 40 years and over, which has practically the same age distribution as that of the male.

From this chart and table it is obvious that pronounced increases have taken place in the death rate from cancer of all forms, and in nearly all the cancers of the different organ seats, the only exception being the rubric "other organs or organs not specified," of which more will be said later.

Comparing the initial and the final rates, the percentage increases given in Table 3 are observed. It is apparent that with the exception of cancers of the skin and cancers of other organs or organs not specified, the increases have been pronounced and striking. Cancers of the peritoneum, intestines and rectum have shown the greatest advance, the percentage increase over the 1900 rate being 148.4. Cancers of the skin, on the other hand, as shown by the chart, have shown no increase in the rate since about 1909, while the curve for other organs or organs not specified is different from that for other varieties of cancer in that the curve shows a pronounced downward concavity.

TABLE 2—*Death Rate from Cancer* *

Year	Cancer, All Forms	Buccal Cavity	Stomach and Liver	Peritoneum, Intestine and Rectum	Female† Genital Organs	Breast†	Skin	Other or Unspecified Organs
1900	212.0	5.50	77.1	19.0	51.0	34.4	7.36	60.75
1901	218.1	6.13	78.1	23.7	56.7	36.6	8.59	55.4
1902	217.4	6.0	80.6	23.69	55.9	39.5	8.06	51.65
1903	227.9	6.84	85.0	22.95	60.4	39.5	8.79	54.85
1904	232.2	7.25	89.2	25.03	61.9	42.3	8.98	50.4
1905	238.8	8.06	90.8	27.48	63.6	41.2	9.13	51.4
1906	240.0	8.11	91.6	29.2	62.6	42.7	8.79	50.3
1907	248.5	8.35	96.2	30.91	65.8	46.6	9.95	47.45
1908	251.0	9.14	99.3	31.44	74.5	50.1	10.91	38.6
1909	259.0	10.08	102.1	34.9	75.7	53.0	11.0	37.37
1910	270.8	10.4	109.0	38.28	77.8	54.2	9.46	38.61
1911	273.8	11.35	107.5	39.5	80.7	55.9	9.81	38.12
1912	278.0	10.82	112.5	38.49	78.8	57.2	10.07	38.91
1913	286.0	10.98	114.0	42.2	82.3	56.5	9.69	40.5
1914	286.0	12.24	107.0	41.88	83.1	64.0	10.19	42.11
1915	293.2	11.51	114.5	44.38	81.2	59.8	9.81	43.45
1916	300.0	10.54	115.1	44.96	83.6	61.6	10.47	47.21
1917	301.4	11.25	114.1	45.0	84.3	62.0	10.13	48.75
1918	299.7	10.74	113.6	46.95	82.6	58.3	9.57	49.03
1919	302.3	11.25	114.1	45.45	84.4	59.5	10.11	50.2
1920	311.4	11.18	116.2	47.2	84.0	62.8	9.38	54.9

* The rate given is that for each hundred thousand of population, aged 40 years and over, all forms and by site of organ affected, in the ten registration states of 1900, for the period 1900-1920

† These rates figured on women, aged 40 and over.

As explained by the Census Bureau, the form of this curve is undoubtedly due to increased precision in stating the site of the malignant growth on the death certificate, the fuller information resulting from the efforts of the Census Bureau and local registrars to improve death registration, permitting the assignment of a larger proportion of cancers to the proper seat of the disease.

Reference to the curve, however, shows us that apparently this gain in accuracy, which produced a striking drop in the mortality rate under this rubric in the period 1900-1909, became stabilized at about that time, as the curve for this classification of cancer shows a steady rise, the percentage increase in the rate from 1910 (the low point) to 1920 being 47 per cent. Since the precision of death certification was presumably as great in 1920 as in 1910, this rise in the death rate curve from that year must be due to an increase in the reported number of deaths of persons 40 years and over from cancers of this class. The types of cancer classified by the Census Bureau under the rubric "cancer of other organs or organs not specified" are cancer of the larynx, lungs and pleura, pancreas, kidneys and suprarenals, prostate, bladder, brain, bones (except jaw), testes, and others of this class.

On the face of things, in the population 40 years and over, and independent of any change in age distribution there has been a pronounced increase in all forms of cancer, and of cancer of nearly all the specified sites. Before accepting this as an actual increase in the cancer mortality, however, we should subject these data to some interpretation.

The validity of mortality returns are, of course, importantly affected by the extent to which causes of death are reported by members of the medical profession and not by laymen, as is too often permitted.

However, so far as the states in question are concerned, inquiry showed that practically 100 per cent. of death returns, for the period under consideration, were signed by duly licensed physicians, and, consequently, the diagnostic error was that inherent in the diagnoses of the medical profession in general, uncomplicated by errors due to the reporting of deaths by laymen.

Statistically, therefore, the mortality statistics of the ten original registration states have a high degree of validity, and from this standpoint are much more reliable than those of certain foreign countries that permit laymen to certify to causes of death.

As Willcox points out, another factor that may alter the reliability of death returns is the extent of available medical services. In regions where physicians are scarce, the death returns are less trustworthy than where they are plentiful.

From this standpoint, however, the ten states considered have little to be desired. In 1906, the total number of physicians in these states was 33,127, a ratio to the population of 1 : 666. In 1921, this number was 39,389. a ratio of 1 : 708.

From this it is evident that in these registration states the ratio of medical men to the general population is very high, more than twice as high, for instance, as in England or in Germany. This betokens a high degree of availability of medical services for diagnosis and treatment of the sick. Moreover, we could not ascribe part of the observed increase in the cancer death rates to increase in the availability of medical services, as the ratio of physicians to the general population was slightly greater during the early years of the period of observation than it was later.

TABLE 3.—*Percentage Increases in Death Rate from Cancer of All Forms*

	Death Rate per 100,000		Per Cent. Increase
	1900	1920	
Cancer, all forms	212.0	311.4	46.9
Buccal cavity	5.5	11.18	103.4
Stomach and liver	77.1	116.2	50.7
Peritoneum, intestines and rectum	19.0	47.2	148.4
Female genital organs*	51.0	84.0	64.7
Breast*	34.4	62.8	82.6
Skin	7.36	9.38	27.4
Other organs or organs not specified	60.75	54.9	9.6 decrease

* Female population 40 years and over

Consequently, since no correction resulting either from lack of medical certification or available medical services need be applied to these rates, the remaining elements that should be examined for trustworthiness, and suitably corrected if need be, consist in allowances that should be made for improvements in the precision and accuracy in returning causes of death, progress in medical diagnosis, and the influence on the cancer death rate due to the changes wrought in the racial stock by immigration.

Even casual examination of the mortality returns over a series of years shows that a pronounced change in the direction of greater precision and detail in the filling out of death certificates must have taken place. An important improvement in this direction is demonstrated, as pointed out by Willcox, by Howard and by others, but the great changes that have taken place in the deaths reported in this age group are due to "indefinite" causes and to senility. This is well shown in Chart 2.

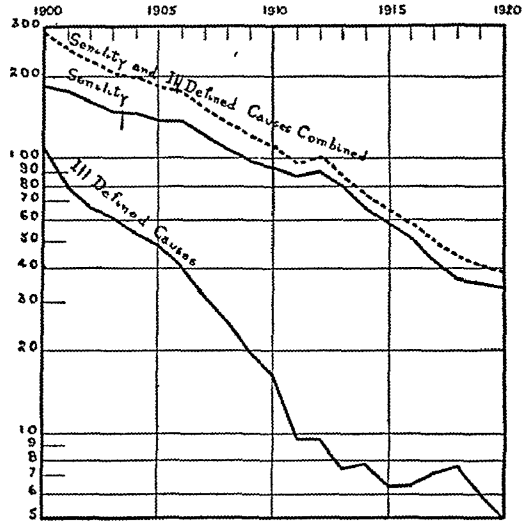

Chart 2—Death rate, per hundred thousand of population, from senility, ill defined causes and the combined rate, in age group 40 years and over, in the registration states of 1900 for the period 1900 1920.

While the general death rate in persons 40 years and over has shown but little change during the period of observation, this chart shows that the death rate from "ill defined" causes fell during the twenty-one year period from 108 to 5, a decrease of more than 95 per cent. In similar fashion, the mortality rate from senility declined from 185.0 in 1900 to 34.1 in 1920, a decrease of nearly 82 per cent.

The drop in the combined death rate from these causes has been from 293 in 1900 to 39.1 in 1920, a decrease of nearly 87 per cent.

Since there has been no significant change during the period of observation in the general death rate of persons 40 years and over, the great reduction in the death rates from indefinite causes and senility must have been effected by a gradual redistribution of deaths formerly reported under these rubrics to other more precise classifications.

The observed reduction in the reported deaths from these causes is thus good testimony to increasing accuracy and precision in death certification. If the 1920 rate for deaths from ill defined causes and for senility had prevailed in 1900, instead of the 15,568 deaths reported under these rubrics, only 2,077 deaths would have been attributed to these causes in the population 40 years and over. For that year, this would leave 13,491 deaths to be redistributed among other more precise classifications. *Here, then, is a source of excess* deaths which, if all assigned to cancer, would much more than obliterate any advances in the cancer death rate.

Of course, there is no justification for any such extreme correction of the cancer death rate, as besides cancer, other diseases, such as *diseases of the circulatory* system, have shown even more dramatic increases than cancer in this age group. However, we must assume that a certain proportion of the deaths certified to formerly as due to ill defined causes and to "old age" were in reality due to cancer. It is of interest to see what adjustment must be made in the cancer death rate if we assign a fair proportion of these deaths to the cancer classification.

Since the number of deaths in persons under 60 reported as due to senility is negligible, we must divide our age group 40 and over into two subgroups, one aged 40-59, and the other, 60 and over.

In the first group, in 1900 there were 1,331 deaths reported as due to ill defined causes and senility, as against 152 in 1920. Had the 1920 rate prevailed in 1900, only ninety-eight deaths would have been reported as due to these causes, leaving a difference of 1,233 deaths to be distributed among other causes of death. In 1920, the deaths from cancer formed 13.7 per cent. of all deaths in this group with the exception of those due to senility and to ill defined causes. So, if for the sake of liberal adjustment we add 13.7 per cent. of the excess deaths to be redistributed, 169 additional deaths attributable to cancer result, to be added to the 5,043 reported deaths, making a total of 5,212 deaths. The adjusted rate resulting from this addition is 138.5 instead of 134.

As the 1920 rate was 176.7, the difference between this and the adjusted 1900 rate for this group is 38.2 instead of 42.7 points. Since 38.2 is about 89.5 per cent. of 42.7, a little more than 10 per cent. of the increase in the cancer death rate in this group may be ascribed to greater precision in certifying causes of death.

Treating the age group 60 and over in similar fashion, we find that in 1900, 14,237 deaths were reported as due to senility and to ill defined causes. Substituting the 1920 rate of 13.2, only 3,033 deaths would have resulted, leaving 12,188 deaths to be reassigned under more definite classifications. Since, in 1920, 10.6 per cent. of all deaths in this age group (except those due to senility and to ill defined causes) were due to cancer, 10.6 per cent. of 12,188 gives 1,292 deaths to be added to the 6,220 reported cancer deaths. This gives an adjusted rate of 484.6, as compared with the observed rate of 401.3. The differences between the reported and adjusted 1900 rate and the 1920 rate are 253.9 and 170.6, respectively, corresponding to percentage increases of 63.3 and 35.2.

Since 170.6 is about 67 per cent. of 253.9, 33 per cent. of the observed increase could be explained by transfer to the cancer column of deaths in which the cause was erroneously reported as due to senility or other ill defined causes.

In making this correction, it has been assumed that the excess deaths are assigned to other causes in the proportion these have to the total deaths from all causes in each age group, the 1920 percentage of cancer, the highest observed, being used in this case.

Willcox believes that this method of correction tends to underestimate rather than overestimate the transfer, since the modern tendency is away from vague and indefinite to specific and definite causes of death. Hence, he believes that there has been a greater tendency to certify cancer, with the increase in precision of death certification, than would be indicated by its chance frequency as a cause of death.

It is believed, however, that the method of correction is liberal for the following reasons: In the first place, the 1920 percentage that cancer formed of all deaths is used, thus representing the more nearly stabilized practices of present day death certification. The circumstance is ignored that, if cancer has actually increased, there would naturally be today a higher percentage of cancer among all deaths than formerly.

Again, we include in the cancer deaths a large number of deaths due to cancer of accessible sites, such as the buccal cavity, breast, female genital organs and skin, about which, as is conceded, errors, so far as death certification is concerned, hardly ever occur. In fact, with regard to such types of cancer, it may be concluded that throughout the entire period of observation the tendency to report a vague and indefinite, rather than a specific, cause of death was negligible as compared to other varieties of cancer, and very much less than for other causes of death, such as organic diseases of the heart.

There is still another correction that must be discussed. While the cancer death rate has been increasing, that due to nonmalignant tumors has been falling. In 1900, the rate was a little over 12 per hundred thousand for persons 40 years and over, while in 1920 it was but 7.9. Had the latter rate prevailed in 1900, only 420 instead of 646 deaths would have occurred. This gives a difference of 226 deaths reported as nonmalignant but which, presumably, were due to cancer.

Let us now review briefly how matters stand as to the various adjustments that should be made in this group.

Table 4.—*Redistribution*

Age Group	Transfers to Cancer From	Deaths
40-59 years	"Ill defined" deaths	169
60 —	"Ill defined" deaths and senility	1,292
40 years —	Nonmalignant to malignant tumors	226
		1,687

In regard to changing age distribution, it has already been pointed out that if the population aged 40 and over were redistributed according to the age constitution prevailing in 1900, the 1920 rate of 311.4 should be somewhat increased to 316.8. This rate is greater than the observed rate of 212.0 in 1900 by 49.5 per cent. In 1900 there were reported 11,263 cancer deaths in this group. As a result of the previous computations, the number of deaths given in Table 4 should be added to this figure.

This total, added to the 11,263 already reported, gives 12,950 deaths. This yields a death rate per hundred thousand of 243.9, 31.9 points higher than the observed rate of 212.0.

This adjusted rate is less than the 1920 rate adjusted for change in age distribution of 316.8 by 72.9 points. This corresponds to an increase of 29.9 instead of 49.5 per cent. As 72.9 is about 69.5 per cent. of 104.8 (the difference between the 1920 adjusted and the 1900 observed rate), a little more than 30 per cent. of the increase in this age group could be attributed to greater precision and more accuracy in returning the causes of death.

One aspect that must be considered in connection with the increase in cancer mortality is the extent to which general improvement in diagnostic skill may have contributed to such increase. It must, however, be borne in mind that here we are dealing, not with improvement in the early diagnosis of cancer, when there is still hope of arresting the disease, but with the diagnosis of cancer in its terminal stages.

From this standpoint, and especially in the recognition of cancers of the accessible sites, such as the buccal cavity, the breast and the female genital organs, it is doubtful whether the physicians of 1900 were much, if at all, inferior to their brethren of today.

Yet the death rates of some of these cancers of accessible sites, such as the buccal cavity, the breast and the uterus, show a higher percentage increase than that of an inaccessible site, such as cancer of the stomach and liver.

This is shown by the following percentage increase in the rates: cancer of the buccal cavity, 103.4 per cent.; cancer of the uterus, 64.7 per cent.; cancer of the breast, 82.6 per cent.; cancer of the stomach and liver, 50.7 per cent.

It is true that the disproportionate increase in the death rate from cancer of the peritoneum, intestine and rectum would indicate some improvement in the diagnosis of these types of cancer. This evidence is somewhat weakened by the failure of skin cancer to advance since about 1910.

While no completely satisfactory explanation is at hand, we may suppose here that the superficial situation, generally lower malignancy, greater amenability both to surgical removal and to radiotherapy, and the much higher average age at death may be cited as factors that would explain the failure of skin cancers to advance *pari passu* with the other varieties.

Before concluding, let me refer briefly to one other point. This is the probable effect on the cancer death rate of the changes in racial stock effected by immigration during this period. It is well known that the character of immigration has been changing. Formerly, immigrants originated mainly from northern and western Europe. Now they come mainly from southern and eastern Europe. The races contributing to the "old" immigration have been the English, Celtic, Teutonic and Scandinavian. The predominant racial stocks in the "new" immigration are Italian and Slavic.

Since the reported cancer death rates in the latter stocks, so far as statistics are available, seem lower, and certainly are no higher than in the racial stock that originated the old immigration, we may assume that the changes in racial stock due to immigration had, if anything, a tendency to lower rather than to raise the prevailing cancer death rates.

CONCLUSIONS

1. There has been a pronounced increase in the observed death rate from cancer in persons 40 years and over in that part of the United States known as the ten original registration states.

2. Part of this increase (about 30 per cent.) is due to greater precision and accuracy in the filling out of death returns.

3. The remainder, however, is an actual increase in the mortality resulting in a death rate between 25 and 30 per cent. higher than it was twenty-one years ago.

ABSTRACT OF DISCUSSION

Frederick L. Hoffman, Newark, N. J.: For many years cancer has been on the increase, and no arguments against this conclusion have stood the test of qualified analysis. Unquestionably, the data are always more or less defective in matters of degree, but this argument can be made against statistics of every nature. When we commenced our agitation in favor of cancer control, the actual recorded mortality from cancer was 75,000, whereas at present it is 110,000. The terminal diagnosis in cancer, at least of the external organs and parts, was probably as good thirty years ago as it is now. Physicians of the past generation were much better observers in matters of detail than physicians of today, who place too much reliance on instruments of precision, tests or mechanical examinations, which cannot properly replace the trained eye, ear and hands. I have little patience with the argument that the physicians of the past were ignorant of obvious cancer occurrences terminating in death in a sufficient number of cases to impair seriously the statistics of the past. Cancer, in brief, and as shown by Dr. Schereschewsky, is unquestionably seriously on the increase. Last year the rate for American cities was the highest on record, while for certain cities the rates are decidedly alarming; but the root of the matter will not be effectively dealt with until the rate is broken up into its component parts and we deal separately with the different forms and types of cancer that affect the human body. The cancer problem is unquestionably the greatest problem before the medical profession at the present time. It will certainly not be solved by those who spend their time in hair-splitting arguments, chiefly for the purpose of controversy, rather than in aid of the search for cancer facts. The statistical aspects of the cancer problem are extremely complex, burdensome, costly and always difficult, but the outstanding results of statistical research are unquestionably useful contributions to cancer knowledge and aid in the search for a better understanding of the true nature of malignant diseases.

Dr. Frank Smithies, Chicago: I am very glad to hear Dr. Schereschewsky discount the remarks of Wells made in Chicago last year. Wells said to a large audience that the reason cancer was increasing was that, through our efforts toward public health, we are increasing the life of the individual, and, in doing this beneficent thing, we were bringing into the cancer class a great many individuals who otherwise would have died from other causes and who would not have reached the cancer age. I think Dr. Schereschewsky's figures prove that Wells was entirely wrong. I can only speak of cancer of the stomach. I have made an analysis on the greatest number of proved instances of cancer of the stomach (921 operatively demonstrated cases). It is interesting to observe that my figures regarding the "hereditary" incidence of cancer as secured by inquiry from patients, and going back only as far as four generations in any family, was 8.5 per cent. This corresponds within 0.5 per cent. of the incidence of spontaneously arising cancers in mice as shown by Maud Slye. I wonder whether any observations have been made by statisticians respecting the total increase in the population of the world with regard to cancer, particularly with respect to the increase of civilized peoples in the world and the increase of cancer incidence. Cancer apparently is a disease of higher civilization; and since gradually the world is accumulating a greater civilized population, possibly it is true that the figures for cancer increase are only keeping pace with the increase in civilized population. This has always appeared to me as interesting, because, as civilized people live faster, eat more, exercise more and are subject to more trauma than uncivilized folk, their organs are put to a greater stress in shorter time than are the organs in less civilized people. They are functionally put to a stress earlier in life and to a greater stress over the period of middle life than individuals not civilized. Their organs earlier reach functional or anatomic senescence. The decrease in skin cancer might be accounted for, perhaps, because during the last two decades a large emigrant population has learned how to keep itself clean. Very likely increased bathing and use of soap and better care of the skin and surfaces of the body have some effect in reducing irritation and thus reducing the incidence of skin carcinoma.

Prof. I. V. Hiscock, New Haven, Conn.: Dr. Schereschewsky has rendered an important contribution to cancer literature. Two years I studied with Dr. Dublin the trend of cancer mortality in a large group of industrial wage earners of the United States and Canada (129 million years of life exposed to risk), for the years 1911-1922. In general, these figures bear out some of the important findings which Dr. Schereschewsky has elaborated today. It is most illuminating when one divides the causes of cancer deaths into the various groups and studies the course of mortality according to factors of age, sex, race, etc. The greatest increase for this industrial group has occurred among the males, and at the older age periods as Dr. Schereschewsky has found for the general population. One of the largest increases is noted from cancers of the peritoneum, intestines and rectum. Cancer of the skin showed a very slight decrease, if anything, while deaths from cancer of the breast showed only very slight increases. A fairly recent note in the *Statistical Bulletin*, Metropolitan Life Insurance Company, calls attention to the importance of the cancers that occurred among the younger people, and I think this group of cancers, as well as those of "other organs and parts not specified," might be studied a great deal more extensively than we have in the past. This could be accomplished by subdividing the cancers of the various organs and parts covered by this important residual group into separate units, for statistical study.

Dr. J. W. Schereschewsky, Boston: The question of the hereditary factor in cancer is, of course, one of great importance. Because of the lack of available data it is not possible at present for any one, so far as I know, to make a thoroughgoing study of this factor in the human race. The hereditary studies that are found in the literature are not sufficiently extensive to give mass value or to exclude the operation of the laws of chance. So far as laboratory observations are concerned, the influence of the hereditary factor appears to be pronounced. In conformity with the experience of Mr. Hoffman and others, the results of this study, which was entered on in an unbiased way, show that the increase in cancer mortality is an actuality. Since this increase is here we must look to factors in our complex civilization which have brought about this great increase in cancer mortality. This means that we must redouble our assiduity along epidemiologic lines with the hope that tomorrow or next year or in the next decade, the solution of the baffling etiology of cancer will be within our grasp. I cannot believe that this increase in cancer mortality is going to continue indefinitely. Like all biologic phenomena, these processes tend to reach a state of equilibrium sooner or later. After the forces that have raised the human race to a new and higher level of susceptibility have spent themselves, I expect to see no further great increase in the cancer death rate.

SCARLET FEVER

ETIOLOGY, PREVENTION BY IMMUNIZATION, AND ANTITOXIC TREATMENT [*]

WILLIAM H. PARK, M.D.
NEW YORK

The etiology of scarlet fever has been under active investigation for many years. Loeffler,[1] in 1884, and later other bacteriologists noted that the hemolytic streptococci were very abundant in the throats of acutely ill scarlet fever patients. Clinicians also noted the fact that in certain cases of wound infection and puerperal fever a scarlet fever-like rash developed. These observations led to the opinion that there was a close relationship between certain strains of hemolytic streptococci and scarlet fever. The majority, however, held that the hemolytic streptococci were merely very important secondary invaders. Repeated attempts by numerous investigators to produce any disease similar to scarlet fever in animals by the inoculation of throat secretion or cultures of hemolytic streptococci obtained from the throats of scarlet fever patients failed. It was therefore necessary to turn to tests on man.

Moser[2] reasoned that, if the streptococcus was the cause of scarlet fever, a curative serum might be produced, and in 1902 published a report of the good therapeutic results obtained by the use of an antiscarlet fever serum produced by the horse after frequently repeated injections had been made of living streptococci together with the broth in which they had developed, so as to get the antigenic value of the organisms as well as of any toxins that might have developed in the broth. The stains of streptococcus used were obtained from a number of toxic cases of scarlet fever.

A Russian investigator, Savchenko,[3] went a step further; he showed, in 1905, that the serum contained both scarlet fever antitoxin and streptococcic bactericidal bodies. He also proved that the filtered broth in which the culture had grown contained a strong toxin. He said:

> Immunizing with the microbes only, it is possible to obtain a very active antimicrobal serum, but not at all antitoxic; vice versa, by immunizing with a toxin, we obtain an antitoxic serum and, therefore, one not acting on the microbes.
>
> In scarlet fever, in which we have severe local infections and at times even general infections, together with the toxemia, we must have in the serum antitoxins as well as germicidal antibodies. Filtrates of our own cultures of streptococci from scarlet fever grown in different combinations of broth proved to be nonpathogenic for rabbits, even in large doses. To conclude from this that there is no poison in the medium would be just as erroneous as to infer that there is no tetanus toxin after we had tried it on chickens, which are insusceptible to it.
>
> It is obvious that cultures grown on 2 per cent. ascitic broth are preferable for toxin production to those grown on sugar broth, even if the organisms are less luxuriant.
>
> The same filtrate, injected under the skin of rabbits in amounts of 5 and even 10 c.c., produced no symptoms except a slight swelling. The filtrate turned out to be just as harmless for other laboratory animals.
>
> These experiments showed that it is possible to obtain a sufficiently strong toxin, but they unfortunately also showed that by means of our laboratory animals it is impossible to gage either the amount of toxin—which is so important for proper immunization—or the amount of antitoxic substances in the serum, which is not less important for curative purposes. For the time being we are compelled to work, so to speak, by "feeling" our way.
>
> As long as the broth cultures were shown to contain toxin, it appeared most proper to immunize horses with living cultures with the accompanying toxic broth, because in this way both antitoxic and antimicrobal substances should be obtained.

After reading the paper of Savchenko, no one can doubt that he produced by the filtrate a true antitoxic serum.

HUMAN IMMUNIZATION AGAINST SCARLET FEVER AND VALUE OF THIS EVIDENCE IN FAVOR OF THE CAUSAL RELATIONSHIP OF STRAINS OF STREPTOCOCCI TO SCARLET FEVER

Gabritschewsky[4] had finished an experimental study on a streptococcic infection of horses in which an appreciable rash developed, and believed he had proved that a vaccine of toxin and dead streptococci was able to develop a moderate degree of immunity. He then turned to the question of utilizing a streptococcus vaccine made from the toxin and the cells of streptococci obtained from scarlet fever. His vaccine was made of bouillon in which the streptococci had grown for four days plus the streptococci themselves. The toxic bouillon containing 3 per cent. by volume of the streptococci was heated to 60 C. to kill the streptococci, and then preserved with 0.5 per cent. phenol (carbolic acid). Three doses were given subcutaneously one week apart. For infants under 2 years the dose was 0.25 c.c.; for children between 2 and 10 years, 0.5 c.c., and for those over 10 years, 1 c.c. The results in children were most important. Langowoi, using his vaccine, found that of 120 children inoculated, 13.3 per cent. developed a fine scarlet fever-like exanthem which was not followed by desquamation. A few developed a sore throat and strawberry tongue, and fewer still vomiting. He states that these symptoms are those which are characteristic of scarlet fever, and these results of the vaccination add an extremely important proof "for the specificity of a scarlet fever streptococcus and its toxin." There is no question that Gabritschewsky considered the bouillon to contain a true toxin, not only from his language, but also because he was in contact with Savchenko, and their articles appear together a little later in the same Russian journal. He found that the second and third injections, although they were twice and four times as large as the first, rarely produced a rash. This he considered as evidence of the rapid development of immunity.

---

[*] This study of scarlet fever was aided by a grant of money from the Milbank Memorial Foundation.

[*] Read before the Section on Preventive and Industrial Medicine and Public Health at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

[*] Because of lack of space, this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints. A copy of the latter will be sent by the author on receipt of a stamped addressed envelop.

Gabritschewsky,[4] in 1907, gives further evidence in favor of vaccination. Of 248 children receiving injections of the vaccine, Nikitin noted the rash in 17.3 per cent. In six he noted a generalized rash, vomiting, a strawberry tongue and an angina. In seven cases, the lymph glands were slightly swollen; in ten cases, albumin appeared in the urine for a day. In one case there was an acute nephritis, which ended in recovery. Twenty-six children who had previously had scarlet fever showed either no reaction or only a slight local swelling. A group of children tested during their fourth week of convalescence showed a greater percentage of reactions than those who had been convalescent for a long time. At Gabritschewsky's suggestion, Langowoi vaccinated twenty children with a vaccine made in the same way as the scarlet fever vaccine from the streptococcus of erysipelas. None of these developed a rash. These cases are too few to prove that the result would have been the same if a larger number had been vaccinated, but they are suggestive of the specific character of the scarlet fever toxin Gabritschewsky closes his article with five conclusions, of which I quote the last two:

> The fact that a scarlet streptococcus vaccine (toxin and culture) is able to produce a scarlatiniform rash and the other symptoms of scarlet fever is a decisive proof in favor of accepting a streptococcus as the specific cause of scarlet fever.
>
> This decisive proof adds a scientific reason for the use of Moser's serum and my vaccine.

Gabritschewsky's death prevented him from following up the practical results of his vaccine. The following statement by Polotevkova[5] is one of several encouraging reports:

> A severe outbreak of scarlet fever took place in my district, with 1,200 cases of the disease. Not only children, but also adults between 20 and 50 years of age were among the sick The form of the disease was also severe, very often involving suppurative affections of the mouth, nose and upper respiratory tract. Owing to the extreme poverty of the peasants of this district, where very often milk could not be obtained for the sick, the only hope was in the preventive immunization In short, the results were such that in the villages in which vaccination took place only one or two or no cases at all were observed; in villages in which no vaccination was carried on, the number of sick would reach from six to 175 cases. The author vaccinated her own three children.

Gabritschewsky considered that he had added to the proof already gathered sufficient evidence so that scarlet fever could be considered to be in the same class as diphtheria. The scarlet fever streptococcus produced its toxins in the throat. The absorbed toxins produced the rash, the fever and the other symptoms due to toxemia. The lowered resistance allowed the scarlet fever streptococci or other streptococci to invade distant parts and make the so-called complications. Additional evidence of the causal relationship was the development of a case of scarlet fever by the accidental inoculation in our laboratory of the throat of one of the assistants by a culture of several strains of streptococci including a scarlet fever strain. A typical case[6] of scarlet fever developed, but attempts to reproduce the disease in animals with the culture failed.

In 1918, Schultz and Charlton[7] described the reaction known by their name. When 1 c.c. of a diluted convalescent serum is injected intracutaneously into the reddened skin of a scarlet fever patient, a blanching occurs in an area several centimeters in diameter. In December, 1923, Mair[8] published further results and concluded that this reaction is due to the action of an antitoxin on the scarlet fever specific toxin. This brings us to the discoveries of the Dicks and of Dochez. In spite of the proof, which was largely unknown to most workers, the majority still believed that the hemolytic streptococcus found in scarlet fever was only an important complicating infection. In October, 1923, the Dicks[9] inoculated five volunteers who had lived in the country, with a streptococcus culture from a case of scarlet fever. One developed a typical case of moderate scarlet fever. The throats of five others were inoculated with the filtrate of a broth culture. None of these developed the disease, but when the same persons were inoculated with the streptococcus, one developed it. This proved that the infection agent was not a filtrable virus attached to the streptococci. It was found by them that the streptococci isolated by them from scarlet fever differed from one another in the ability to ferment mannite. The first two cases had been caused by an organism that fermented mannite. The Dicks then tried out the effect in the human skin of the toxin discovered by Gabritschewsky and Savchenko. They found that weak solutions of the toxin may be employed in skin tests to determine suscepti-

Table 1—*The Dick Test at Different Age Groups (Zingher)*

Age	Total Tested	Per Cent Dick Positive
0- 6 months	29	44 8
6 12 months	52	65 3
1- 2 years	233	71 6
2- 3 years	204	64 2
3- 4 years	241	60 5
4- 5 years	264	48 4
5-10 years	1,955	33 6
10-15 years	2,965	22 8

bility to scarlet fever. The toxin is first carefully standardized and diluted so that 0.1 c.c. represents a skin test dose. The test consists of an intradermal injection of exactly 0.1 c.c. of the skin test dilution on the flexor surface of the forearm. The reaction is observed at the end of twenty-four hours. An area of reddening 2 cm. in diameter indicates marked susceptibility; 1 cm. in diameter, some degree of susceptibility to scarlet fever.

Table 3.—*Immunizing Results of Three Injections of 300, 500 and 1,000 Skin Test Doses of Scarlet Fever Toxin Given at Intervals of One Week*

Before Injection Reaction to Dick Test	Results of Retest: Two Weeks After Last Injection	Four Weeks After First Injection
	2 = 2 +	
	2 = $+^1$	50 per cent. immune
10 + + or + $+^1$	1 = +	
(Strong reactors)	5 = −	50 per cent. still susceptible
	4 = +	68.5 per cent. immune
35 $+^1$ or +	7 = ±	20 per cent. doubtful
(Moderate reactors)	24 = −	11.5 per cent. probably susceptible

Results with Injections of Double the Foregoing Amounts

Before Injection	Two Weeks After First Injection	Four Weeks After First and Two Weeks After Third Injections
12 + + or + $+^1$	3 = 2 +	2 = $+^1$
(Strong reactors)	3 = + Week	1 = ±
	2 = ±	9 = −
	3 = −	
	1 not tested	
	27 per cent. immune	75 per cent. immune, 16 per cent. not immune, 8 per cent. doubtful

+ + Indicates a Dick reaction of 2 cm. in diameter and + of 1 cm.
$+^1$ Indicates more than + and ± less than +.

In a series of skin tests, reported in January, 1923, the Dicks found a positive or strongly positive reaction in 41.6 per cent. of the persons who gave no history of scarlet fever, and negative or only slightly positive reactions in all the convalescent fever patients tested. Zingher's observations fully corroborate these findings and show that the results in age groups from the Dick test were very similar to the results from the Schick test.

This skin test was developed before they attempted to produce experimental scarlet fever with the type of streptococcus that does not ferment mannite. In selecting their volunteers for inoculation with this type of streptococcus, they chose one with a negative skin reaction, and one with a positive reaction. The two volunteers were inoculated with the same culture. The one with a negative skin test remained well, while the volunteer who had shown a positive test developed scarlet fever.

In the instances in which they had an opportunity to observe the skin reaction before and after an attack of scarlet fever, it was positive before the attack, and negative during convalescence. It is now known that there are about 10 per cent. of exceptions to that rule.

These authors [10] also found that if persons with positive skin tests received convalescent scarlet fever serum intramuscularly, their skin tests became negative. With more definite doses than Gabritschewsky used they then attempted to immunize persons against scarlet fever and utilize later their skin test to determine the development of antitoxic immunity. They found that, by proper dosage, they were able to immunize persons with positive skin tests so that their skin tests became negative and they did not contract scarlet fever on exposure. They report a series of 125 persons exposed to scarlet fever. In this series, sixty-three showed negative skin reactions, and were not immunized. Fifty-two had positive skin tests, and were immunized with toxin. None of these persons contracted scarlet fever. They emphasize the importance of carrying the immunization to the point of a negative skin test. By the employment of three graded doses of toxin, they have been able to eliminate severe reactions.

While the Dicks were adding to the proof as to the causal relationship of certain strains of streptococci to scarlet fever, Dochez [11] was developing an antitoxic serum through a method developed by himself of injecting subcutaneously into animals masses of nutrient agar infected with scarlet fever streptococci. These injections, repeated from time to time in increasing amounts during from six to eight months, were found to develop a potent antitoxin. The serum of horses that had been subjected to such injections was found to give the Schultz-Charlton test, even when the serum had been diluted several thousand times. The serum was used in cases in New Haven and in New York, and the same results were regularly obtained as had been formerly obtained with unstandardized serum by Moser and Savchenko; but now the potency of the serum was established by the striking results with the Schultz-Charlton reaction. These were a demonstration to all that antitoxin was truly present.

Shortly after Dochez announced his serum, the Dicks made a report on the production of antitoxin by the toxic filtrate standardized by their method. Whether the Dochez method or the various modifications of the toxin with or without killed or living streptococci will finally be adopted remains for further comparative tests to decide. This will depend largely on the value of an antimicrobal substance in the serum. The results with the Dochez serum or the Dick serum agree absolutely with the reports of the use of the Moser serum.

ACTIVE IMMUNIZATION

Earlier in this paper I gave the work of Gabritschewsky and his followers. In the light of the Dicks' researches and the rashes that developed, it can be estimated that the Russian infants received about 1,000, 2,000 and 4,000 skin test doses and older children 2,000, 4,000 and 8,000, or perhaps double that amount. With the Dick test, the dosage can be standardized and the immunity results determined by retesting from time to time. The scarlet fever toxin is much less injurious to the local tissues than the diphtheria toxin, so that there is no need of adding antitoxin to it or of changing

Table 4.—*Results in Dick Positive Children Three and One-Half Months After Receiving Three Immunizing Injections of Approximately 1,000, 2,000 and 4,000 Skin Doses*

	Reaction Three and One-Half Months Later	
11 + + or + $+^1$	1 = +	63 per cent. immune
(Strongly positive)	3 = ±	27 per cent. doubtful
	7 = −	9 per cent. probably susceptible
10 + or $+^1$	1 = ±	90 per cent. immune
(Moderate reactors)	*1 = pseudo	10 per cent. doubtful
	8 = −	
Total 21 cases	1 = +	76 per cent. immune
	4 = ±	19 per cent. doubtful
(Strong and moderate reactors)	15 = −	4 per cent. moderately susceptible
	1 = pseudo negative	

* Gave + reaction with and without mixture with a sufficient quantity of convalescent serum to neutralize the toxin.

[10] Dick, G. F., and Dick, Gladys H.: The Prevention of Scarlet Fever, J. A. M. A. 83: 84 (July 12) 1924.

[11] Dochez: Proc. Soc. Exper. Biol. & Med. 4: 184 (Jan.) 1924.

it by formaldehyd. Yet, as the Dicks state, such chemical modification resulting in a decreased toxicity or toxoid is desirable, if it can be demonstrated that it accomplishes immunization with fewer doses or in a shorter time. The most suitable dose of toxin varies with conditions. If scarlet fever is prevalent, it is very desirable not to give sufficient toxin to make a rash in any of the very susceptible children, for there is no certain way of determining in such a case whether it is a case of light scarlet fever or of a toxin rash. Even if cultures are made, it is possible that streptococci which produce the scarlet fever toxin will be present, and yet the case will be due to a toxic rash. If, however, no scarlet fever is in the neighborhood, a slight scarlet rash is of no importance and larger doses can be given. The Dicks give an interesting summary of the relation of the total skin doses to the immunity results.

They advise skin doses for the first 500, for the second 1,500, and a considerably larger dose for the third.

Original Investigations.—Tables 3, 4, 5, 6 and 7 show the results in our tests following the injection of from 600 to 10,500 skin doses. The tests in these tables, with the exception of the one by Zingher, were made by Schroder and read by her, Williams and myself.

TABLE 5.—*Results of Five Immunizing Injections at the End of Three and One-Half Months Approximately 500, 1,000, 2,000, 3,000 and 4,000 Skin Test Doses*

	After Three and One-Half Months	
32 + + or + +^{1}	1 = +	81 per cent. immune
Strongly positive cases	5 = ±	= 17 per cent. probably immune
	23 = −	= 2 per cent. probably susceptible
	*3 + ± negative pseudo	
36 + or +^{1}	34 = −	
Moderate reactors	*1 = + negative pseudo	100 per cent. immune
	*2 = ± negative pseudo	
69 + to + +^{1}	1 = +	91 per cent. immune
All positive reactors	5 = ±	7 per cent. probably immune
	57 = −	1 per cent. probably susceptible
	1 = + negative pseudo	
	5 = ± negative pseudo	

* 1 + and * 5 ± are considered negative pseudo reactions because of an equal reaction in the control neutralized by convalescent serum.

The persistence of the acquired immunity following injections remains in doubt. With small injections, such as in the cases recorded in Table 7, many of the originally very positive cases have after a year relapsed, while the originally moderately positive cases have generally continued to hold their immunity or to increase it.

With much larger injections, such as those recorded in Tables 4 and 5, the immunity response is so much greater that it is hoped that the marked positive cases will not only develop immunity but hold it for a period of years.

We note in these tables that the moderately reacting cases develop complete immunity much more readily than the strongly reacting cases; again, that the response is quicker than after diphtheria toxin-antitoxin or toxoid injections. This corroborates the views of Gabritschewsky and the statements of the Dicks that immunity develops in many within one or two weeks.

The results of a second series of injections in those who have not responded to the first series have been excellent.

The persistence of a negative Dick reaction in those found to be negative: Observations on several thousand children by Zingher and Schroder at different intervals of time up to thirteen months have shown that a naturally acquired immunity is usually persistent for at least one year. Only about 2 per cent. of those originally negative have been found to change. It is fair to assume, therefore, that as in the case of naturally acquired immunity to diphtheria, the immunity to scarlet fever naturally acquired is apt to remain. This finding, which is in accord with the findings of the Dicks, encourages us to hope that, with larger and perhaps more numerous doses, even the very positive cases may acquire such a high degree of immunity that it will last for at least a few years. We already have the knowledge that these immunizing injections are very useful in stopping an outbreak of scarlet fever.

TABLE 6.—*Immunity Results After Four Weeks with Three Injections of Scarlet Fever Toxin (Dick Test)—1,200 Skin Test Doses in All (Zingher)* *

	Dick Retest After from Four to Five Weeks						
			Dick Positive and Combined			Dick Negative and Pseudo	
Institution	Per Cent. Positive Dick at Original Test	Total Retested	Number Positive As in Original Test	Number Less Strongly Positive	Per Cent. Less Strongly Positive	Number	Per Cent.
Hebrew Orphan Asylum	29.2	143	19	20	14.0	104	72.7
New York Orphanage	44.4	91	10	36	39.5	45	49.4

Total		274	41	66	24.0	167	61.0

* Doses given: under 12 years, 200, 500 and 500 skin test doses at weekly intervals; over 12 years, 200, 500 and 1,000 skin test doses at weekly intervals.

THE SERUM TREATMENT OF SCARLET FEVER AS OBSERVED AT THE WILLARD PARKER HOSPITAL

Scarlet fever antitoxin was first administered by us in January, 1924. This was made possible through a supply of serum by Dr. Dochez. The first serum was only moderately potent, and in the doses given by the intramuscular method, the results though good were not striking. In January, 1925, it was decided to give it to alternate patients, and in severe cases to give it intravenously. The antitoxin most used was our own preparation obtained from two horses that had received increasing toxin injections for nine months and more; but in about one fourth of the cases we used a new preparation of the serum sent us by Dochez. The result of the intravenous injection was so striking that the medical board decided in March, 1925, to give all patients having a rash and a temperature of 101 F. or higher antitoxin and to give it to alternate patients having a temperature lower than 101. It was given intravenously in all severe cases.

TABLE 7.—*Results of Injecting 100, 200 and 400 Skin Test Doses as Shown by Retest Five and Thirteen Months Afterwards at St. Dominicks*

	Five Months After	Per Ct.	Thirteen Months After	Per Ct.

by Dr. Schroder	+ = 27	= 33.3	± = 14	doubtful
	± and − = 46	= 56.8	± or − = 57	immune
	Total 81		Total 100	

The antitoxin serum was given by Dr. Mildred McBride, the assistant resident physician who was in charge of the scarlet fever service at the Willard Parker Hospital. The attending physician on duty and I watched with her the effects of the treatment. The potency of the antitoxic serum was tested either by the Schultz-Charlton blanching test or by the more accurate Dick neutralization tests of the toxin. The potency ranged from 50 to 150 units per cubic centimeter; that is, 1 c.c. of the serum neutralized between 5,000 and 15,000 Dick test skin doses of toxin.

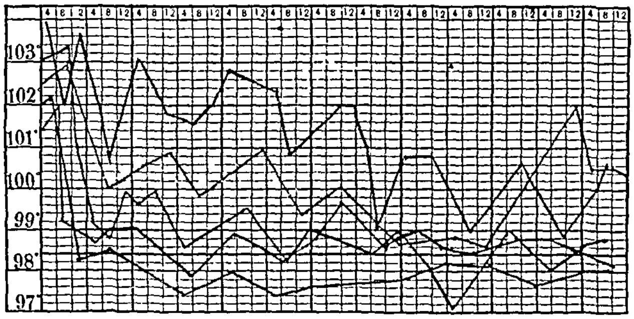

Chart 2.—Temperature curves in five uncomplicated cases after an intramuscular injection of antitoxin

Most of the serum was not refined. About fifty patients however, received the refined antitoxic globulin solution. The therapeutic results were alike, but rashes occurred in about 60 per cent. after the injection of the unrefined serum, and in only about 30 per cent. after injection of the refined. The rashes and other symptoms of serum disease that did occur were more severe with the unrefined. No serious after-effects occurred in any case, but the serum sickness in some was very annoying. The dosage was determined by much the same principles that govern the dosage of diphtheria antitoxin. A sufficient dose should be given at the earliest possible moment. An amount should be given in the first dose to make and keep the fluids of the body antitoxic. If, however, the temperature rises after the drop, a second injection should be given. The size of the dose is influenced by the weight of the individual and the severity of the case. Whether a late case in which there is still a marked rash should be treated with larger doses than an early case of equal severity is in our belief doubtful and remains still a matter for further investigation. Intravenous injections of sufficient size give the most striking results. The fluids of the body become quickly antitoxic, as shown by the Dick test. This, when done even an hour or two afterward, is always negative, if a sufficient dose has been given, and remains negative if done later in the disease.

The results from sufficiently large intramuscular injections are certain, but they develop more slowly. The Dick test is positive for from six to twelve hours after an intramuscular injection. It then becomes negative.

The results as noted at the bedside in the majority of patients are very striking. The higher the temperature and the more toxic the case, the more striking will be the results if the serum is given very early in the disease. After an intravenous injection in an early uncomplicated case, the patient, as a rule, finds within a few hours that the throat is less sore, the mind clears, vomiting ceases, the appetite returns, and the temperature and pulse begin to fall. Within from six to eight hours, a delirious and a very sick patient is often convalescent. With a larger dose given intramuscularly the same results follow, but more slowly. With insufficient dosage there is a less rapid improvement, and the toxic symptoms may return. Our results were practically identical with those reported by Blake[12] and Birkhaug.[13]

The following two cases showed favorable results after intramuscular injection in the first and intravenous injection in the second:

Case 1.—G. C., a boy, aged 7, was sick two days with headache and vomiting. A rash developed on the morning of the 23d. On admission in the afternoon, the temperature was 103 F.; pulse rate, 150; rash marked, and throat inflamed. The Dick test made on admission was positive. The severity was from moderate to severe. The patient was given intramuscularly 40 c.c. (about 3,200 units) of Dochez' antiscarlatinal serum. On the 24th, the rash was greatly lessened; the Dick test made in the morning was negative, and the temperature was 101 F. in the morning and 100 F. in the afternoon. On the 25th, the rash was gone; the temperature, 99.6 F. The patient made an eventful recovery (Chart 1).

Case 2.—A. K., a man, aged 32, who had a sore throat on the 17th, with a rash appearing on the 19th, was admitted early in the afternoon on the 20th. The temperature was 102 F. and rose to 104 F.; the pulse rate was 130. The throat was inflamed. Adenitis was present, and the patient was fairly toxic. He received on admission 2,400 units of antitoxic serum intravenously. Within two hours he felt improvement. At the end of six hours, the temperature had fallen to 98.8 F., the rash had faded and the patient felt almost well. Convalescence was uncomplicated (Chart 1).

Chart 2 gives the temperatures of five patients who received intramuscular injections. The drop in temperature is comparatively slow. Two of these patients received insufficient amounts of antitoxin.

Chart 4 gives the composite temperature curves of twenty-five severe, twenty-five moderate and twenty-five light cases of scarlet fever treated with serum during the first three days of the disease and an equal number without.

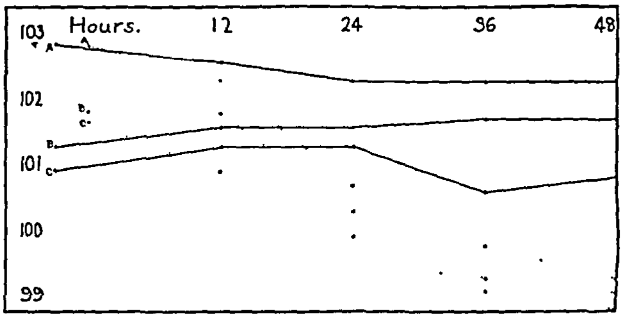

Chart 4.—Average temperatures of seventy five patients treated with serum and seventy five patients treated without serum. solid line, patients treated without serum; dotted line, patients treated with serum. There were twenty five cases of each. *A*, severe, *B*, moderate; *C*, mild.

Complications.—The antitoxin has little effect on complications, such as infection in the tonsils, in the middle ear, in the mastoid, in glands of the neck or in the endocardium, when they have already developed; but before they have developed the antitoxin appears to be of service in preventing their occurrence. This is probably due to the raising of the resistance of the local tissues and of the body as a whole so as frequently to prevent or restrict the invasion of the body by the streptococci. These streptococci may be those producing the

13 Birkhaug Bull Johns Hopkins Hosp **36,** No 2, p. 134.

scarlet fever or other varieties. An interesting case was that of a woman sick with toxic scarlet fever complicated by severe erysipelas. The delirium vanished, the vomiting ceased, the temperature was lowered and the rash faded, but the erysipelas ran its usual course. Table 8, which shows the complications developing in seventy-five cases that were treated and in seventy-five that were untreated, indicates a favorable influence of the antitoxin in preventing complications. As long as the rash remains, antitoxin is indicated.

The cases in Table 8 are not strictly comparable, since the severe and moderate cases which were not treated with serum are taken from 1924, while the serum-treated cases occurred in 1925. The diagnosis of nephritis is based mostly on the urine examinations and is probably not wholly accurate. The kidney complications, on the whole, are seen to be decidedly less in the cases treated with antitoxin early, but the other complications are about the same.

Reduction in Mortality.—During the year 1924, when scarlet fever was very light, 569 patients with scarlet fever were admitted to the hospital. About forty of these received scarlet fever antitoxin. The mortality among the 569 patients was 2.8 per cent. During April and May of this year, when all patients with cases of any severity and with a rash were receiving serum, there were 220 admissions. Of these, six patients, or a percentage of 2.7, died.

These figures, considered without a knowledge of the cases, would be very misleading; but they cause one to wonder what proportion of the 150 or more deaths from scarlet fever which occur yearly in New York can be eliminated by the use of serum. In three of the six fatal cases the patients were admitted so late that they were absolutely unsuitable for antitoxin, but in three of them they were admitted on the third day. The histories of these six fatal cases are as follows:

Case 3.—A child, aged 11, admitted thirty-eight days after the development of scarlet fever, showed symptoms of meningitis. Death occurred three weeks later. Necropsy showed several small brain abscesses.

Case 4.—A child, aged 7, admitted on the ninth day of disease, with double otitis media, septicemia and signs of endocarditis, died in three days.

Case 5.—A man, aged 35, admitted in the afternoon on the sixth day of the disease, with an intense rash still present, and a temperature of 104.8 F., received 60 c.c. of Dochez serum intravenously (about 5,000 units). The temperature dropped within six hours to 99.5 but rose the following afternoon, when he died. Necropsy showed purulent bronchitis and toxic changes.

Case 6.—A patient, aged 23, ill three days, with a marked rash, marked pharyngitis with grayish exudate and a temperature of 103.6 F., received 30 c.c. of serum intravenously (about 1,800 units). Complete anuria was present during the first thirty-six hours. The temperature dropped to 99 in eight hours following the administration of the serum, but rose again. The rash remained pronounced for three days. The patient died on the fourth day after admission.

Case 7.—A patient, aged 21, following a kidney operation at another hospital, developed scarlet fever, and was sick three days before admission. The patient appeared toxic with a generalized hemorrhagic rash. The temperature was 103 F. The patient was given 30 c.c. of serum (about 2,000 units) intravenously. The temperature dropped 4 degrees in eight hours, but rose in the afternoon just before death. The rash remained, but was somewhat faded.

Case 8.—J. M., aged 3½ years, was taken ill with vomiting, May 10, developed a rash on the 12th, and was admitted on the 13th, with a temperature of 104.8 F., a generalized hemorrhagic rash and an intense pharyngitis with exudate on the tonsils. Several hours after admission, 30 c.c. of antitoxic serum (about 2,400 units) was given intravenously. The temperature dropped to 100 F., but rose to 102 in afternoon. Another 40 c.c. of serum was given intravenously. The temperature dropped to 101, but rose in the evening to 103 and continued between 101 and 103 until death, May 20. The rash did not fade until the 19th. Necropsy revealed an ulcerative inflammation of the mouth, esophagus and stomach.

In the last three of the six fatal cases, the serum was given about as quickly as would generally be possible. Nevertheless, the patients responded only temporarily and inadequately to the antitoxic serum. It is possible that if the serum had been given immediately after the development of the rash, a better result might have been obtained or perhaps much larger or repeated doses of antitoxin might have done more good. There is also the possibility that some of the cases presenting septic rashes are not ordinary scarlet fever and are due to streptococci that differ in the type of their toxins from those produced by the ordinary strains. We have evidence of such difference, but unfortunately we did not isolate and test the streptococci from these cases for their toxins.

Table 8.—*Complications Developing in Scarlet Fever in Seventy-Five Cases Untreated with Serum and in Seventy-Five Early Cases Treated with Serum*

Twenty-Five Mild Cases:					
Without serum..	4	0	8	3	0
With serum......	0	4	6	2	0

CONCLUSIONS ON THE THERAPEUTIC VALUE OF ANTITOXIN

The antiscarlatinal serum produced by Moser and Savchenko produced the same therapeutic results as that now produced by the Dochez method or by the subcutaneous injection of known doses of toxin. The value of the earlier products was greatly handicapped by the lack of any means such as the Schultz-Charlton and Dick methods for estimating their antitoxic potency. Because of this lack of knowledge, serum weak in antitoxin was undoubtedly frequently used with disappointing results.

The antitoxic serum should be given in sufficient amount as early in the disease as possible. When thus given, the results in most cases are strikingly favorable. The early use of antitoxin probably frequently prevents the development of complications.

Antitoxin is useless after the rash has disappeared and has no effect on the later septic complications.

In moderate cases it should be given intramuscularly. In severe or toxic cases it should be given intravenously. As a rule, a single dose of sufficient size is enough, but in severe cases in which the symptoms return, a second dose in from twelve to twenty-four hours is often desirable. It is too early to state whether the serum should be given in very mild cases, since the serum sickness is often more annoying than the scarlet fever.

The refined antitoxic serum produces fewer and less severe rashes than the unrefined, and should in time be the only preparation used. A unit should be adopted, so that results from different dosages may be compared. The one suggested at a recent meeting of immunologists in Washington seems to be suitable.

One unit is defined as the amount of antitoxin that neutralizes 100 skin test doses (Dick), as determined by an intracutaneous test in man. A dosage between 2,000 and 10,000 units will probably suffice in the great majority of cases. A few of the failures of antitoxin may be due to the fact that some toxic cases may be due to streptococci that produce other toxins than are neutralized by the antitoxin used. This is an interesting problem for further study. Whether it will be of marked advantage to combine an antimicrobial serum with the antitoxic serum is still doubtful, but merits careful investigation.

Such a serum used alone in the past has given doubtful results, but combined with antitoxin it may add to the benefit produced. There would thus be a return to a serum such as was used by Moser, but with knowledge of the potency in both the bactericidal and the antitoxic properties.

Department of Health.

ABSTRACT OF DISCUSSION

Dr. Abraham Zingher, New York: I shall present my own results with the Dick test and active immunization with scarlatinal toxin before the Section on Pharmacology and Therapeutics. The work covers more than 15,000 Dick tests and 2,000 active immunizations with scarlatinal toxin. I wish to emphasize just now the logical and careful manner in which Dr. Park has given us the historical development of the serum treatment of scarlet fever, which was brought to the attention of the medical profession twenty-five years ago by Moser in Austria and twenty years ago by Sovchenko in Russia. The serums recently described by the Dicks and by Dochez do not differ from these older serums, and if anything are inferior to Moser's serum, which is a polyvalent antibacterial and strongly antitoxic serum. Such a serum will probably be the ideal future therapeutic agent in the treatment of scarlet fever. The clinical results published by Blake and his associates are no better than those so carefully reported by Moser and Escherich in Austrian and German literature in 1903. There is no reason, therefore, why one commercial manufacturing laboratory should claim that the Dochez serum is the best, and another firm, that the Dick serum is the best. The work of Gabritchewsky and his associates, who immunized between 1906 and 1910 more than 50,000 people in Russia with a broth culture of the scarlatinal streptococcus, definitely indicates, as Dr. Park has pointed out, that Gabritchewsky and the other Russian observers fully identified the specific hemolytic streptococcus as the cause of scarlet fever. The careful description given by Gabritchewsky of the rashes and other constitutional symptoms following in 15 per cent. after the injection of his toxin-vaccine shows that he was fully cognizant that the organism produces a soluble toxin similar to the diphtheria toxin. Moreover, he stresses that the rashes were noted because the toxic broth culture was injected into human beings who are susceptible to the specific action of the toxin, while animals appear to be immune to it. The constitutional symptoms following the injections of Gabritchewsky's toxin-vaccine were exactly the same as those described by the Dicks in their publication a year ago. One can therefore state that neither the toxin nor the antitoxic serum is a new discovery. The work of the Dicks consisting of actual production of scarlet fever in human beings and the development of a test along the lines of the Schick test has helped in clearing up the etiology of scarlet fever and will be of value in the future control of the disease. I cannot close my remarks without mentioning one thing that occurred to me when I heard Dr. Lindsley Williams speak just now on the possibilities of establishing a federal health department in this country. In the early part of 1919, while in France, I went to see Dr. Haven Emerson in Tours and said to him that no mention was made in the covenant of the League of Nations, which had just appeared, of an international health bureau to correspond to the proposed international labor bureau. He suggested that it would be useless to look forward to the establishment of such a bureau when, in a country like ours, we have not yet succeeded in grouping our health activities under a federal health department. But hope springs eternal, and today we have a health section of the League of Nations. There is no reason why we should not have in this country a highly efficient federal health agency with a responsible cabinet officer. Beneficial results would not be slow in coming; also we would not have to hear with jealousy from our Canadian friends, as we heard last night, that the government there has ruled that medical men and women are the only ones who can be called today in Canada by the title "doctor," while all the others of the variegated therapeutic fraternity are known as "mechanics."

Dr. William H. Welch, Baltimore: I desire to correct the statement inadvertently made by Dr. Zingher that the covenant of the League of Nations said nothing about protection and promotion of health as one of the obligations and functions of the league. There is an important provision in the covenant covering this question of health, and as should be well known, although apparently it is not, there has been created an active and most useful health section of the league, which is engaged in important activities in the field of international health.

Dr. Matthias Nicoll, Jr., Albany, N. Y.: I would ask a question for my guidance as a health officer, as to whether Dr. Park believes that testing for immunity and conferring of immunity on susceptibles have reached such a point that the state health officers should advocate this as a general procedure and start a campaign to that end in the same way that is done in the case of diphtheria? As state commissioner of health I have felt like waiting on further results in the city of New York, believing it would be a mistake in view of the active campaign for eradication of diphtheria to add still another campaign which involved, to my mind, some difficult procedures on the part of general practitioners and local health officers, and up to the present time I have confined my action to distributing at various stations throughout the state supplies from the state laboratory of the scarlet fever antitoxin for curative purposes, and not emphasized or started a campaign against scarlet fever. I have been tremendously impressed with the therapeutic value of this remedy, which I have myself observed with Dr. Park at the Willard Parker Hospital. I should like to hear Dr. Park's opinion as to the best course for state and local health officers to advocate regarding testing for immunity to scarlet fever and inducing immunity in susceptibles on a large scale.

Dr. William H. Park, New York: Just a word about Dr. Zingher's statement that Moser had a better serum than that produced by Dochez or Dick. We had no way of standardizing Moser's serum; some of it was probably very good and some very poor; that is probably the reason it fell into disuse because it could not be standardized at that time. As to the question of refined and unrefined, we have had our hospital use the unrefined in about 150 cases and the refined in about seventy-five. There has been no difference in the effects except in the rashes, other symptoms and serum sickness. There have been no bad results. As to the amount of toxin used in the Dick standard test, of course we must realize that the Dicks, just like Schick, are trying to separate the susceptible from those who are not. That is a difficult problem. If it is a little too strong there will be too many positives; if it is too weak there is the possibility of having people who are susceptible pronounced immune. As to Dr. Nicoll's question, it seems to me we have sufficient evidence to say that a negative Dick test in untreated cases indicates a fairly permanent immunity. Those who pass the test are probably immune for many years, maybe for life. As to immunization in general, I would advise at present to use it only when scarlet fever is more or less a possibility. In such instances people are interested and immunization will be of value to stop the present outbreak. I would not press it until another year has gone by at least, and until we know how permanent is the immunity and the number of doses that are best to give. We advise at the present time 500, 1,000 and 2,000 and then a final one of 5,000 skin doses.

NOVASUROL IN THE TREATMENT OF ASCITES IN HEPATIC DISEASE *

LEONARD G. ROWNTREE, M.D.
NORMAN M. KEITH, M.D.
AND
CHARLES W. BARRIER, M.D.
Fellow in Medicine, the Mayo Foundation
ROCHESTER, MINN.

Novasurol is a double salt of sodium mercurichlorphenyl oxycetate with diethylbarbituric acid (barbital), and contains 33.9 per cent. of mercury. It was introduced originally by Zieler[1] as a remedy for syphilis, but at present it is being used largely as a diuretic. Since the beginning of the nineteenth century, mercury compounds have been recommended as diuretics by certain authors, but these have failed of general application because of ineffectiveness or of untoward or toxic effects. Novasurol has an advantage over metallic mercury and calomel in that it is freely soluble in water and may be administered by subcutaneous, intramuscular or intravenous injections.

Our interest in this drug was incited by a statement of Wenckebach, in whose clinic Saxl and Heilig[2] first proved its efficacy in cases of cardiac dropsy, in the treatment of which its best results have been obtained. It often succeeds in cases in which the purin derivatives and digitalis have failed. Apparently it has also proved useful in some cases of edema of renal origin, as shown by Keith, Barrier and Whelan,[3] and it will unquestionably play an important part in the future in the treatment of certain types of nephritic edema.

ACTION OF NOVASUROL

Saxl and Heilig[2] demonstrated a relative and absolute increase in the excretion of chlorids in the urine. Bohn[4] proved that this occurred in normal rabbits. Nonnenbruch[5] and Mühling[6] showed that novasurol caused an increase in the excretion of chlorids in the urine in normal persons, but that diuresis did not always occur. Keith and Whelan[7] confirmed this finding in two normal persons and in the dog. They also found that, under the influence of this drug, there was a relative and absolute increase in the output of sodium in the urine.

According to the literature, the results from novasurol in cases of ascites and edema of portal cirrhosis are unsatisfactory. Brunn[8] states that diuresis failed to appear in cases of cirrhosis of the liver, and that headache and vomiting followed its use in one case. Mühling[6] records increase in icterus following its use, evidence, he believes, of injury to the liver. Hassencamp[9] failed to induce diuresis in two cases of hepatic cirrhosis. On the other hand, Bleyer[10] obtained a good effect in one case, and Fodor[11] maintains that novasurol is effective in the ascites of cirrhosis and in polyserositis, provided the patient presents a good blood pressure. Rowntree and Barrier[12] have reported some excellent results in cases of cirrhosis of the liver and Banti's disease.

The clinical material serving as the basis of this report comprises twenty cases in all, including ten cases of portal cirrhosis, two of portal cirrhosis and cardiac decompensation, two of syphilitic cirrhosis, two of Banti's disease, two of neoplastic disease with metastasis to the liver, one of polyserositis, and one of polycythemia with chronic endocarditis and myocardial insufficiency. In each of these cases the ascites was marked, and in most of them constituted an outstanding clinical feature. Demonstrable cardiac and renal insufficiency was lacking in all but three, but in these it unquestionably constituted an additional factor in the causation of the edema, as shown in the accompanying tabulation.

The medical treatment of ascites is similar to that of general edema, especially in the restriction of water and salt, the control of diet and the use of diuretic drugs. Novasurol has been used alone in certain cases with striking results. However, the best results have come from the combined use of novasurol intramuscularly or intravenously, and ammonium chlorid by mouth, together with a controlled diet of a fixed low-water and low-salt content.[13] Novasurol is given in doses up to 2 c.c. intramuscularly or intravenously at intervals of from three days to a week. The tolerance of this drug is first determined by the administration of from 0.5 to 0.75 c.c. intramuscularly. Ammonium chlorid is administered by mouth in divided doses up to 10 gm. daily, and is best given in the crystalline form in capsules of 0.75 gm. or 1.50 gm. In nineteen of the twenty cases, diuresis has resulted from this treatment.

In eight cases, during the diuretic periods, the urinary excretion of chlorin and sodium was relatively and absolutely increased; that of potassium and calcium usually absolutely increased. These results indicated a marked increase in the total output of fixed base. Actual determination of the total fixed base, by the method of Fiske,[14] accurately confirmed the increase indicated by the analysis of the individual bases. The total output of urea, ammonia and total nitrogen was also slightly increased. The greater and more constant diuresis, which we have obtained with novasurol combined with ammonium chlorid, appears to be due to the increased chlorin in the tissues, rather than to the decrease in the alkali reserve.

Blood analysis in many of these cases failed to show any constant changes in the concentration of hemoglobin, serum protein and chlorin. On two occasions, there was a fall in the serum chlorin during diuresis, as

has been reported by Crawford and McIntosh[15] in their cases of cardiac edema. Nor did we find any constant changes in the concentration of the inorganic ions in the serum. The carbon dioxid capacity of the plasma remained unchanged during the diuresis.

Novasurol produces an increased excretion of sodium and chlorin in the urine. Whether the seat of this specific action is in the kidney only, in the tissues generally, or in both, has yet to be determined. Combined studies of the constituents in both blood and urine have so far failed to reveal the exact site of its action, and further experimental work is required.

RESULTS IN CIRRHOSIS OF THE LIVER

Novasurol has been employed in this series in ten cases of cirrhosis of the liver associated with ascites, and has caused diuresis in all. Repeated periods of diuresis have caused the disappearance of ascites and edema in seven cases, and to a large extent, also, the evidences of collateral circulation. After the fluid has disappeared, the patients have improved remarkably in health and strength. Case 1 represents an excellent result and one that is rather characteristic of the group as a whole.

CASE 1.—*Atrophic portal cirrhosis of the liver.* A man, aged 63, admitted to the Mayo Clinic, Nov. 11, 1924, complaining of enlargement of the abdomen (ascites), had had an acute attack of right-sided abdominal pain associated with hematuria on Thanksgiving Day, 1923, attributed, by the family physician, to renal calculus. The patient had suffered from bilateral inguinal hernia for fifteen years. He complained of a bloating sensation and diarrhea for one month during the spring of 1924. In July, he found that the hernial contents were reduced with more difficulty and that they frequently "slipped out" during the night, causing discomfort and loss of sleep. Operation, in August, revealed free abdominal fluid, and the examination showed enlargement of the spleen. His local physician made a diagnosis of cirrhosis of the liver.

---

[15] Crawford, J. H., and McIntosh, J. F.: Observations on the Use of Novasurol in Edema Due to Heart Failure, J. Clin. Investigation 1: 333-358 (April) 1925.

Early in September, the abdomen began to enlarge and the quantity of urine to diminish appreciably. This progressed steadily, and with it slight swelling appeared in the feet and ankles and lower part of the legs. His weight remained almost stationary, with fluid collecting in the abdomen, but the face, arms and legs became noticeably thinner. During the two weeks before admission, he experienced a growing tendency to weakness with occasional slight dizziness, and to difficulty in starting urination, especially when the daily quantity was small.

He weighed 195 pounds (88.6 kg.). The abdomen was markedly distended with fluid. Collateral channels over the abdomen and thorax were moderately well marked. The face, arms and legs were moderately emaciated. The tongue was red and parched. The tonsils were enlarged, and fluid pus could be expressed. An enlarged cervical gland was found, and on biopsy proved to be inflammatory in nature. The heart measured 2.5 cm. to the right and 14 cm. to the left, the apex being in the fourth intercostal space. A systolic murmur was audible over the entire precordium, and the aortic second sound was accentuated. The peripheral vessels were sclerosed 2. The blood pressure was 160 systolic and 100 diastolic; the pulse was 100. The lungs were clear. Other than ascites 3, nothing could be made out in the abdomen. Moderate edema was evident in the legs and in the sacral region. The eyegrounds were clear except for mild senile fibrosis of the retinal arteries. The urine was scanty, from 200 to 300 c.c. daily, with a trace of albumin. The hemoglobin was 55 per cent.; the erythrocytes numbered 3,480,000, and the leukocytes 3,000, with neutrophils 53 and lymphocytes 45 per cent. The phenolsulphonephthalein output was 45 per cent., and the blood urea 40 mg. for each 100 c.c. of blood.

The patient was admitted to the hospital. A diagnosis of cirrhosis of the liver was made, the abdomen tapped, and 12 liters of fluid withdrawn. At this time, the liver was found to be markedly enlarged and firm in consistency, extending 5 cm. below the left costal margin. The fluid rapidly reaccumulated during the next week, and a second paracentesis was considered. His weight was 181 pounds (82.7 kg.), and the blood pressure 140 systolic and 54 diastolic. There was retention 3 of phenoltetrachlorphthalein, but the serum bilirubin was normal (1.4 mg.). The stools were light in color; the urine did not contain bile.

The patient was placed on a diet; fluids and salts were restricted, and novasurol was given. Diuresis followed each injection, and the weight rapidly diminished as the ascites disappeared. Tests of hepatic function, made ten days later, showed a normal amount of bilirubin in the serum (1.6 mg.), dye retention 2, and a positive fructose tolerance test. The effect of novasurol is shown in Chart 1. At the end of four weeks the patient had lost 33 pounds (15 kg.); the girth had decreased from 110 to 85 cm., and fluid could be no longer detected in the abdomen. The spleen was easily palpable; in fact, a mass was visible on respiration, and the edge of the liver could be felt almost 4 cm. below the xiphoid, but not under the right costal margin. The patient had gained materially in strength and was walking about with great comfort. The hemoglobin was still 55 per cent., and the erythrocytes numbered 3,150,000, but the leukocytes had increased to 6,600. The patient was dismissed in excellent clinical condition.

The patient returned, March 19, 1925, for a review of his condition. He reported that it had been satisfactory since leaving the hospital about three months before. He had taken ammonium chlorid at intervals, but had had no novasurol since his dismissal. He had gained 12 pounds (5 kg.), and there was some tendency to recurrence of fluid in the abdomen (ascites 1), but little or no evidence of collateral circulation. The spleen was easily felt, but the edge of the liver was just barely palpable; edema 1 to 2 of the lower extremities was present. The urine was free from albumin and casts; the specific gravity was 1.027. The stool gave repeated positive tests for blood and bile. The tests of hepatic function showed dye retention 2 and serum bilirubin 0.9 mg. The patient was again admitted to the hospital and given ammonium chlorid for four days, with no loss in weight. Following his first dose of novasurol, a diuresis reaching 3,700 c.c. resulted. After a second dose of novasurol four days later, the fluid in his abdomen disappeared entirely. He was given a third dose, but the output of urine was only 1,000 c.c. He was dismissed, April 6, 1925, entirely free from ascites, and advised to continue the weighed low-fluid, low-salt diet with about 600 c.c. of extra fluid. He returned, July 8, 1925, weighing 130 pounds (60 kg.), and reported that he had had hematemesis two weeks previously. The retention of the dye was graded 1, and the serum bilirubin was normal.

RESULTS IN SPLENIC ANEMIA, BANTI'S DISEASE

In both of our cases of Banti's disease, the ascites was extreme, and in both there had been many previous tappings. They both responded to novasurol with results that are little short of marvelous.

Case 16.—*Banti's disease and ascites.* A man, aged 53, was admitted to the clinic, Oct. 14, 1924, with the diagnosis of Banti's disease and ascites. His chief complaint was ascites and hematemesis for a period of three years. Between 18 and 43 years of age, the patient had been well except for "summer attacks of heavy pain across the lower abdomen, lasting from three to four days and relieved by catharsis." In July, 1906, he had had an attack of severe pain across the lower abdomen with a temperature of 101 F. He was placed on a liquid diet and lost 30 pounds (13.6 kg.). In August, 1914, he had had a sudden attack of pain in the region of the appendix. An operation was performed for acute appendical abscess. A hernia occurred at the site of the operation. In December, 1920, after a heavy meal, a sudden gastric hemorrhage occurred, with a loss of 1,500 c.c. of blood, and melena for five days thereafter. One month later his physician found an enlarged spleen, for which two roentgenologic treatments were given, with the result that the spleen became definitely smaller. In December, 1922, intestinal obstruction occurred in the region of the hernia, but the patient recovered satisfactorily. June 7, 1923, the hernia was repaired. In December, 1923, the veins over the abdomen, particularly in the region of the hernia, became greatly distended; ascites appeared; two severe gastric hemorrhages occurred, and the spleen became markedly enlarged. During the last year the patient had been tapped twenty-one times, and during the six weeks before admission he had become gradually weaker.

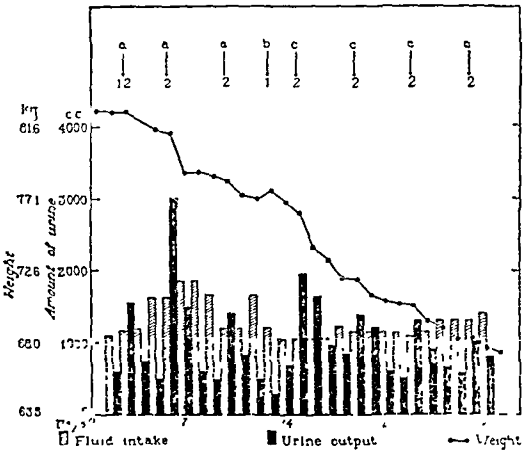

Chart 1 (Case 1).—Fluid balance, diuresis and weight loss under novasurol: *a*, intramuscular injection; *b*, intra-abdominal; *c*, intravenous. In the charts, the shaded columns indicate fluid intake; solid columns, urine output; solid line, weight.

The patient was considerably emaciated. Pyorrhea 1 to 2, and marked ascites 3 were present. The spleen was palpable three finger-breadths below the costal margin. The blood pressure was 118 systolic and 78 diastolic; the pulse was 92. The urine was clear; the specific gravity was 1.010; the reaction was acid, with no albumin, sugar or bile, but a good trace of urobilin and urobilinogen. The hemoglobin was 63 per cent.; the erythrocytes numbered 4,360,000, and the leukocytes 2,400. The coagulation time was seven minutes, and the bleeding time five minutes. The resistance of the erythrocytes was somewhat increased. A gastric test meal showed a total acidity of 20, free hydrochloric acid 8, and total quantity 100 c.c. The blood Wassermann reaction was negative. Examination of the fundi was negative except that there was a suggestion of fibrosis in the retinal arteries. The tonsils were somewhat enlarged. Studies of hepatic function showed a dye retention 1 and normal values for serum bilirubin. The patient was placed in the hospital on a medical regimen, which consisted of restriction of fluids, a diet of 1,500 calories and 40 gm. of protein Charts of fluid balance were kept; 3 gm. of ammonium chlorid was given daily, and injections of novasurol were administered intramuscularly with results as indicated in Chart 2. No untoward effects followed any of the injections, except that the patient complained some of pain and tenderness following the first intramuscular injection. At the end of six weeks, the ascites had entirely disappeared, as had also the abdominal collateral channels. The weight decreased from 157 to 123 pounds (71.2 to 55.8 kg.). The gain in health and strength was equally striking, the patient walking on some days as much as 7 miles without undue fatigue. He returned home and took up his business responsibilities with considerable zest.

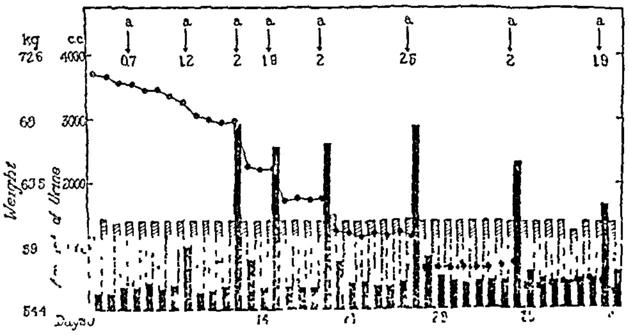

Chart 2 (Case 16) —Fluid balance, diuresis and weight loss under novasurol. *a*, cubic centimeters intramuscularly.

Reports from the patient's local physician three months later indicated that there existed a constant tendency for the abdominal fluid to recollect. However, a weekly injection of novasurol sufficed to prevent the development of edema and ascites. Subsequently, the patient visited Europe and while there consulted Muller and Wenckebach, who advised against operation. In a letter received June 15, 1925, the patient stated that he was quite recovered, in excellent physical condition, and in need of no further medication.

RESULTS IN SYPHILITIC CIRRHOSIS

Novasurol has been utilized in several cases of ascites associated with syphilis of the liver by O'Leary.

CASE 12.—*Syphilitic cirrhosis.*—A man, aged 50, was admitted to the clinic, Sept. 16, 1919, complaining of a pain in the pit of his stomach, and of having had sour eructations after meals for two years. The serum Wassermann reaction was positive. A diagnosis was made of aneurysm of the aortic arch, and tertiary syphilis. He was seen again in April, 1920; November, 1920; June, 1921; February, 1922, and February, 1923. His condition was fairly good until March, 1924, when he returned complaining of a brassy cough and considerable dyspnea on effort, which had begun with a left-sided pneumonia a year earlier. The cords showed no lesion or evidence of paralysis at that time. There was no edema of the extremities. The aneurysm of the aortic arch could be outlined by roentgen rays. On the last examination, April 7, 1925, he stated that he had felt well until March 1, 1925, when he began to feel below par, and noted a fulness in the abdomen. The legs became edematous, and there was moderate dyspnea.

Physical examination revealed ascites 4, with marked abdominal collateral circulation. The heart measured 18 cm. in the fourth interspace, and there was a dilated arch with systolic and diastolic murmurs at the base. There was slight edema of the lower extremities.

A diagnosis of aortic aneurysm with myocardial degeneration, and syphilitic cirrhosis with ascites, was made and the patient was admitted to the hospital. Ammonium chlorid and novasurol were given with a resulting diuresis, after which there was considerable improvement (Chart 3). Because of nausea, the ammonium chlorid was discontinued and the novasurol repeated, with a loss of 18 pounds (8.2 kg.) in three days. Tests of hepatic function at this time showed dye retention 3, latent jaundice, and serum bilirubin 2.4 mg. The patient was given seven injections of novasurol during the following month, with a fair response on each occasion. He had lost 30 pounds (13.6 kg.), but was still not entirely free from edema. The abdomen was still very prominent, and there was slight distention of the lateral veins. There was ascites 3. The specific gravity of the urine was 1.020; it was acid in reaction, and the urine contained albumin 1. The hemoglobin was 55 per cent.; the erythrocytes numbered 3,090,000, and the leukocytes 3,500. The phenolsulphonephthalein return in the urine was 55 per cent. in two hours. The blood urea was 43 mg.; creatinin, 3.8 mg.; uric acid, 4.9 mg., and chlorids, 580 mg. for each 100 c.c. of blood. The carbon dioxid combining power was 56 per cent. by volume, and acid hemoglobin 14 gm. per cent.

The patient was placed on a weighed diet, low in salt and containing 800 c.c. of fluid with 600 c.c. of additional fluid, and was given 10 gm. daily of ammonium chlorid in capsules. Under this combined treatment, a further loss of 15¼ pounds (6.9 kg.) was effected in eight days. On being sent home, he was given the low salt diet with restricted fluid intake, Blaud's pills, and tonic remedies, and was told to pay special attention to rest and exercise. A note received June 18, 1925, indicates that there is a slight tendency for the fluid to recollect.

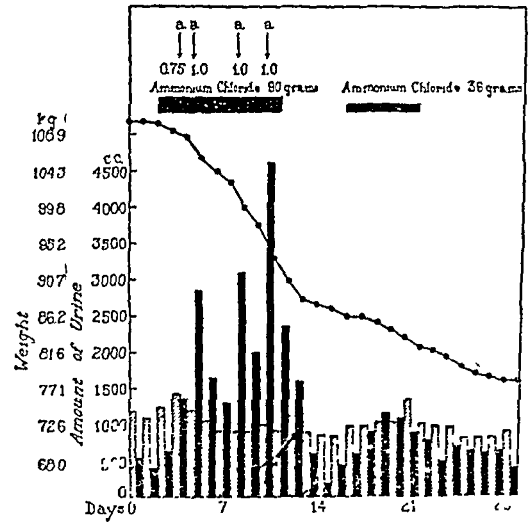

Chart 3 (Case 12) —Fluid balance with combined use of ammonium chlorid and novasurol: *a*, cubic centimeters of novasurol.

RESULTS OF TREATMENT OF ASCITES AND EDEMA IN CASES OF PORTAL CIRRHOSIS WITH MYOCARDIAL AND RENAL INVOLVEMENT

CASE 18.—*Portal cirrhosis with myocardial and renal involvement.* A man, aged 63, who came to the clinic, Jan. 20, 1925, complained chiefly of discomfort due to fluid in the abdomen. His present illness came on gradually. In November, 1922, slight edema of the extremities was followed by ascites. There was no preceding dyspnea, palpitation or cardiac distress. Paracentesis was performed on eight different occasions, from about 8,000 to 10,000 c.c. of rather dark colored fluid being removed at each tapping. The relief obtained by these aspirations lasted only about five or six weeks. During the last year, the patient had been treated at Clifton Springs, by means of calcium chlorid, and had lost 70 pounds (31.8 kg.) in four weeks. He had continued this medication until six weeks before coming to the clinic. At that time, because of marked pruritus, the calcium chlorid was discontinued. He also became careless in his diet and gradually regained his former weight and girth.

At the time of admission, the patient's weight was 244 pounds (111 kg.). There was marked ascites, and none of the abdominal organs were palpable. There was considerable edema in the sacrolumbar region and the lower extremities, but none in the upper.

The urine showed a specific gravity of 1.030, a faint trace of albumin, and occasional hyaline and granular casts. The blood urea was 54 mg. and the creatinin 2.2 mg. for each 100 c.c. The hemoglobin was 70 per cent.; the erythrocytes numbered 3,800,000, and the leukocytes 5,200. The blood Wassermann reaction was negative. Tests of hepatic function showed dye retention 4 and serum bilirubin 2.1 mg. The electrocardiogram showed auricular fibrillation, a right ventricular preponderance, and inverted T wave in Leads I and II. The roentgenogram showed a maximal cardiac enlargement with apparently slight dilatation of the aorta. The diagnosis was portal cirrhosis, myocardial degeneration, and chronic nephritis.

The patient was put on a controlled low-fluid, low-salt diet consisting of 40 gm. of protein. Ten grams of ammonium chlorid was administered daily in capsules. Small doses of novasurol (from 0.75 to 1.5 c.c.), given intravenously every four days, resulted in marked diuresis. The patient lost 85 pounds (40.9 kg.), as shown in Chart 4, and at the time of his dismissal, April 1, 1925, was entirely free from ascites and edema, and felt very well. The edge of the liver could now be felt 8 cm. below the right costal margin. The patient was very active and able to walk several miles every day. On dismissal, he was advised to continue the same regimen, to take a diet of 2,000 calories with 50 gm. of protein, and 1,000 c.c. of extra fluid. A report received three months after dismissal states that there had been no return of symptoms, and that his weight is 157 pounds (71.4 kg.).

In this case, there were three possible etiologic factors for the edema and ascites—myocardial degeneration, cirrhosis of the liver, and renal insufficiency—all of which were definitely present. The fact that novasurol was so efficacious indicates that not one of these conditions per se contraindicates its use.

RESULTS IN PICK'S DISEASE, OR CHRONIC POLYSEROSITIS

Case 17.—*Chronic polyserositis.* A girl, aged 20, came to the clinic with anasarca, and was admitted as an emergency case.[16] Her chief complaints were dyspnea, palpitation, fatigue and anasarca. Her present illness was insidious in onset, beginning two and one-half years before, with menstrual changes and loss of weight. Menstruation became irregular and scanty, and finally disappeared nine months before admission, at which time edema appeared for the first time. She also noted precordial distress and palpitation on exertion. In April, 1923, she had two attacks of hemoptysis, about 200 c.c. of blood being lost each time. Subsequently, the precordial distress was more pronounced, and medical advice was sought. At this time, she was in the hospital for two months, and irregular fever was noted. She lost her voice, as a result, it was thought, of involvement of the recurrent laryngeal nerve. Her heart was extremely large. The condition was diagnosed pericarditis with effusion. She was tapped five times, and on one occasion 1,500 c.c. of straw-colored fluid was removed, supposedly from the pericardium. Guinea-pig tests were negative. Following this, she improved markedly until February, 1924, at which time she noted that the upper part of the abdomen was becoming bloated. This persisted, and later the lower extremities became edematous, and she became extremely dyspneic. There was a hacking cough, and some expectoration. The urinary output was decreased. Fluids were restricted, but there was no deprivation of salt.

On admission, the patient was dyspneic and had a pasty complexion, and there was obvious edema of the face. She had typical watch-crystal nails, an injected throat and small tonsils, also prominent cervical veins. The chest was asymmetrical. There was dulness to percussion over both apexes, with limited respiratory movement and breath sounds more marked over the left lung. The right side contained a moderate amount of fluid. The left side of the chest showed moist crackles throughout. The heart was large, extending 12.5 cm. to the left, and 5 cm. to the right at the fourth interspace. The abdomen was distended, and the liver showed enlargement 4, extending almost to the umbilicus. There was fluid in the flanks, and edema 3 of the extremities extending to the thighs. The heart sounds were distant. A roentgenogram of the chest showed a dense thickening of the pleura at the left base. Fluoroscopy revealed no evidence of pericarditis with effusion or pericardial adhesions. The urine was small in quantity, about 150 to 200 c.c., with albumin, trace to 2, and occasional hyaline casts. The phenolsulphonephthalein excretion was 35 per cent. in two hours, and the blood urea was 13 mg. for each 100 c.c. The hemoglobin was 76 per cent.; the erythrocytes numbered 4,100,000, and the leukocytes 5,200. Repeated analyses of the sputum revealed no tuberculosis. The Wassermann reaction was also negative. The stools gave a positive benzidin test for blood. An electrocardiogram showed inversion of the T waves in Leads I, II and III. The diagnosis was made of Pick's disease, general anasarca with ascites, hydrothorax, probably hydropericardium, chronic enlargement of the liver, and possibly chronic passive congestion of the kidney.

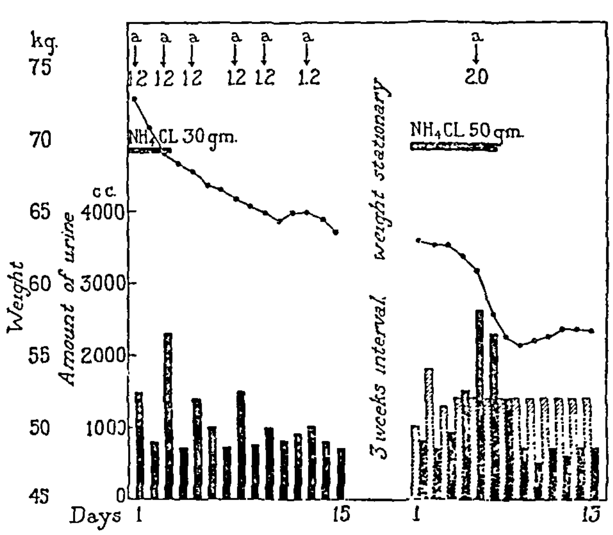

Chart 4 (Case 18).—Fluid balance with combined use of ammonium chlorid and novasurol: *a*, cubic centimeters of novasurol intravenously.

The patient was placed in bed with a back rest, put on a Karell diet, and treated with digitalis. The systolic blood pressure was 100, the diastolic 70. The weight was 137½ pounds (62.5 kg.) and was reduced to 130 pounds (59 kg.) under this regimen. At this time, ammonium chlorid, 8 gm. daily, was given by mouth, and novasurol was administered four days later. The course of events under this ammonium chlorid and novasurol treatment is shown in Chart 5. This treatment was continued for a month. The patient received in all eight doses of novasurol. Diuresis was pronounced following each injection. On some occasions, the fluid output reached from 2 to 3 liters. The weight was reduced from 137 to 97 pounds (59.2 to 44.5 kg.). On dismissal, the patient had lost every trace of edema. She had been on a weighed, low-fluid, low-salt diet of 2,000 calories with 400 c.c. of extra fluid daily, and she was advised to continue this after leaving the hospital.

---

[16] The patient's physician, in his letter of reference to the clinic, stated that the anasarca was of a most obstinate type and had resisted all forms of treatment.

RESULTS IN AN UNUSUAL CASE OF POLYCYTHEMIA, ASCITES AND HYDROTHORAX COMPLICATING MYOCARDIAL INSUFFICIENCY[17]

Case 20.—*Polycythemia and myocardial insufficiency.* A man, aged 35, admitted to the clinic, May 21, 1925, complained of distress in his stomach, and of dyspnea. Aside from diphtheria and scarlatina during childhood, he had never been ill until he had influenza in 1918, from which he made a good recovery. About five years before his present illness, he had had frequent severe epistaxis. About two years before admission, he first noticed dyspnea following the extraction of two teeth. His gums bled profusely, and the hemorrhage was controlled with difficulty. His condition returned to normal in about a month. During harvest time in 1924 he again became dyspneic, and in November he contracted a severe cold, and his condition become progressively worse. He had also a bad cough, and some mucus in his throat. Later, his abdomen became distended and caused him considerable discomfort. Just prior to his admission, he had been in bed on a Karell diet for six weeks, with no benefit. He had noticed recently a gradual diminishing urinary output.

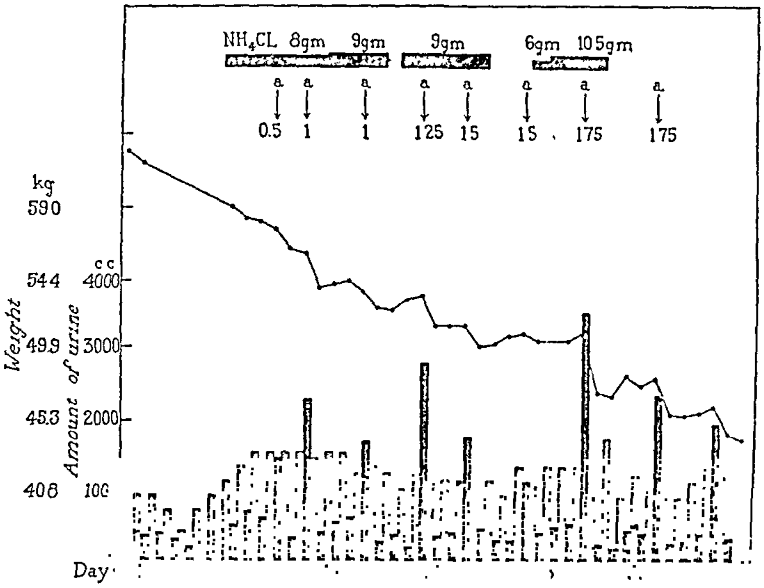

Chart 5 (Case 17).—Fluid balance with combined use of ammonium chlorid and novasurol: *a*, cubic centimeters of novasurol intravenously.

When the patient arrived at the clinic, there was moderate edema of the feet and ankles, and he complained of a dull pain in the right upper abdominal quadrant. He was definitely orthopneic and edematous. There was no striking enlargement of lymph nodes. There was slight pulsation in the veins of the neck. The heart beat was regular, and the organ measured 3 cm. to the right and 12.5 cm. to the left in the fourth interspace. There was a visible and palpable impulse in the sixth space, with a suggestion of a thrill, and a definite diastolic rumble over the apical region. The lungs were clear, except for an area of definitely impaired resonance at the right base, and a few crackling râles at both bases. The liver seemed enlarged on percussion, but the edge could not be definitely felt on account of the ascites. There was peripheral sclerosis 1 to 2. The blood Wassermann reaction was negative. The urine contained a slight amount of albumin and a few hyaline casts; the specific gravity was 1.025. Repeated examinations of the stool showed no parasites or ova. The phenolsulphonephthalein return was 65 per cent. The hemoglobin was 80 per cent.; the erythrocytes numbered 5,600,000, and the leukocytes 8,100. The differential count showed eosinophils varying from 13 to 39.1 per cent. The blood volume was high, 144 c.c. for each kilogram of body weight, and the hemoglobin was 23 gm. per cent. by the acid hematin method. An outstanding feature of the blood picture was the large number of eosinophils. The nonprotein nitrogen was 60 mg. for each 100 c.c., although the blood urea was only 20 mg.; the creatinin was 1.4 mg., and uric acid 6.6 mg. The amino-acid nitrogen was 11.9 mg. A culture of the blood gave no growth on brain broth or blood agar in forty-eight hours. Tests of hepatic function showed dye retention 2 and serum bilirubin 1.59 mg. Roentgenograms of the chest disclosed a slight amount of fluid in the right base. The culture of this fluid was negative. The electrocardiogram showed sinus tachycardia, right ventricular preponderance, notched T wave in Leads I, II and III, and diphasic T wave in Derivation III.

The patient was first treated with digitalis, but did not respond well. Later, he was given ammonium chlorid and the weighed diet, with little or no effect. He was given novasurol three times along with the ammonium chlorid, with a definite diuresis on each occasion. There has been considerable subjective improvement with the relief from the abdominal tension, and the clearing of his hydrothorax. On dismissal, the patient was free from edema (Chart 6).

The gross results in regard to diuresis and weight in the entire series are shown in the tabulation.

COMMENT

The results obtained from the use of novasurol in this series of cases are unquestionably better than we have observed in similar cases with other methods of treatment. Ascites and edema, which have resisted other measures in many instances, have promptly and completely yielded to the regimen here presented.

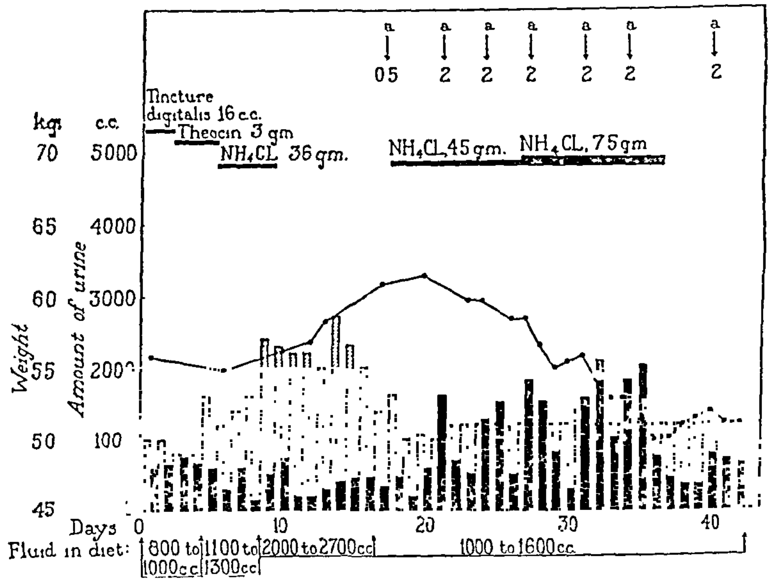

Chart 6 (Case 20).—Relative effect of digitalis, theocin, ammonium chlorid and the combination of ammonium chlorid and novasurol.

The restriction of water is indicated and of undoubted value, and raises the question of the advisability of forcing the water intake in cases of cirrhosis of the liver prior to the appearance of ascites, a practice advocated in some of our leading textbooks of medicine. The low-fluid, low-salt diet is also an important consideration. Recent work in the field of edema emphasizes the importance of the part played by sodium, and thus knowledge of the sodium intake and its restriction is obviously important. The restriction of sodium is more important than the restriction of chlorids, since diuresis results and edema disappears under the forced administration of chlorids, as the ammonium salt. Ammonium chlorid in itself is a powerful diuretic, in this connection excelling calcium chlorid in the treatment of edema. Finally, novasurol is one of the most potent diuretic agents ever introduced into medicine. By itself, it is often capable of increasing the urinary output in a most striking manner. If success is lacking or only partial, its action is usually strikingly enhanced by the adoption of a low-fluid, low-salt diet and the administration of ammonium chlorid.

---

[17] The diagnosis of polycythemia can be established reasonably well, although the number of erythrocytes does not reach the upper limits of normal, and the hemoglobin by the Dare method is so much less than the acid hematin estimation.

The results from novasurol have been consistenly good, except in three instances. In one case (Case 4), diagnosed hepatic (biliary) cirrhosis with splenomegaly and ascites, diarrhea resulted together with a slight increase in the preexisting jaundice. However, the patient had previously suffered from colitis and dysentery, with suspicious organisms in the feces. Despite definite diuresis, and a decrease in the ascites with the loss of 11 pounds (5 kg.), the treatment was not considered successful. A second patient with portal cirrhosis (Case 7) lost 10 pounds (4.5 kg.) in the course of two weeks, with moderate diuresis on each of four occasions following the injection of novasurol. However, the fifth injection failed to induce diuresis, and an effort was made to administer ammonium chlorid both by mouth and intravenously, but it could not be tolerated so that resort was had to paracentesis. In a third case, entire lack of cooperation precluded a satisfactory trial of the drug.

Concerning permanence of results, little can be said. In every instance in which ascites was entirely controlled, the results have been far beyond our expectations. In some instances, there has been a tendency to recurrence of ascites and edema subsequently, but this has been controlled by the use of novasurol at intervals of from one to two weeks or more. In other cases, the edema has entirely disappeared, and has shown no tendency to recur.

With the clearing up of ascites in portal cirrhosis, the general health and strength are markedly improved, the abdominal collateral channels disappear almost entirely, and the patient passes from a condition of serious illness to one closely approaching normal. This confirms the results reported by Fudor and Bleyer. In view of certain previous experiences reported in the literature, that is, the lack of effect, or actual harm, in some cases of cirrhosis of the liver, it is obvious that great care is necessary in following the course of events in such cases while treatment is being given. Whereas novasurol, ammonium chlorid or the low-salt diet alone may fail, their combination may effect excellent results.

These results in the treatment of ascites with novasurol have a special interest in view of the current theories of the cause of edema. They certainly argue against a purely mechanical cause. No constant changes in blood pressure have been demonstrated during or following the administration of the drug. It would appear, therefore, that changes of a physicochemical nature, probably affecting the cellular colloids, are responsible for the ascites and edema. It may be that sufficient attention has not been paid to the normal water excreting function of the liver.

These results indicate that ascites of hepatic disease, particularly that of cirrhosis, can usually be adequately controlled by medical measures.

THE PHENOMENA CONCERNED WITH "REACTIONS" FOLLOWING THE TRANSFUSION OF BLOOD

CLINICAL AND EXPERIMENTAL OBSERVATIONS [*]

RALPH A. KORDENAT, M D.
AND
FRANK SMITHIES, M.D.
CHICAGO

Clinically, it is recognized that the intravascular introduction of blood to a subject from an individual of homologous species is a therapeutic procedure of first rank. At times, blood transfusion may be the only agency through which life may be saved or prolonged.

While differences of opinion exist as to the method of choice in transfusion, there is unanimous agreement that the factor of greatest importance, with respect to the results, is the blood itself. In this viable fluid tissue lie the potentialities for clinical betterment or for harm. Numerous contributions have emphasized the benefits that have followed blood transfusion.[1] The harmful consequences of the procedure have been dwelt on indifferently by clinicians and in incomplete or detached fashion by laboratory workers. Our report is an attempt to describe (*a*) the type of unwished-for events that may follow blood transfusion and to discuss the nature of such phenomena, and (*b*) to suggest means by which undesirable sequelae may be avoided.

RESPONSES OF RECIPIENTS TO BLOOD TRANSFUSION

The procedure is either beneficial or harmful. Consequent on a successful transfusion, the subjective and objective evidences of well-being and of increased physical and functional efficiency are readily demonstrable. Transfusion to counterbalance massive blood loss, from whatever cause, is accompanied by the most striking and permanent benefits. When the ailment treated is an organic, metabolic, septic affection or a hematologic dyscrasia, though the immediate transfusion response may be satisfactory, the persistence of that result may be brief. It cannot be foretold. Quite often, the subject's condition is better out of all relation to the volume of blood transfused. Again, large transfusion volumes may not be followed by proportionate improvement. Something more fundamental than what is covered by mere increase in blood volume by transfusion requires explanation before one can understand the mechanism that controls responses.

Before describing undesired transfusion responses, it would seem advisable to note why the classification given below has not been generally recognized. Descriptions of the recipient response vary noticeably.

[1] Hunt, J.. Collected Papers from the Mayo Clinics, Philadelphia, W B Saunders Company, 1919, p 672. Pemberton, J.: Ibid, p. 540. Stetson, R E: Am J. M. Sc **168**: 534

With the possible exception of reports on the acute, or what is commonly called the hemolytic, reaction, post-transfusion phenomena have been considered loosely. Wide discrepancies occur in the communications of scattered observers and even in those from different men working in the same institution (Hunt,[1] Pemberton,[1] Unger,[2] Lindeman [3] and Bernheim [4]). Study of the reports shows quickly that the variations in records are due to clinicians and laboratory workers endeavoring to apply the same language to different observations or different language to factors that essentially are similar. If one regards transfusion as a biologic, immunologic, chemical and clinical experiment, analysis of the reports of recipient response phenomena indicates that often the experiment has lacked all controls; the agents interacting were dissimilar as to kind and quantity; apparatus, time, environment, technical skill, etc., all differed; and yet, a like answer to the problem was expected or, if not secured, was explained away by theory, which theory quickly became the parent of many equally unproved corollaries. The effects of whole blood are compared in relation to citrated, salted or defibrinated blood; with blood at body temperature, or cooled, or refrigerated and later heated; with blood directly passed from vein to vein, or through cannulas, needles, mixing chambers, valves, stopcocks, rubber, glass or metal tubes or cylinders; with blood exposed to air and mechanical trauma and blood not so changed; small volume transfusions (at hourly, daily or weekly intervals) are compared with large volumes, given rarely or frequently—and, in each instance, the blood given may or may not have been physically, chemically or biologically changed from normal. One can multiply almost endlessly the factors that have made it impossible to arrive at a correct appraisal of reaction phenomena, or to compare the results from one set of observers with those of another. It is evident that, not infrequently, so-called reactions in recipients are in no wise due to the effects of transfused blood, as such, and to that alone. Certainly, one should discuss transfusion responses only when all phases of the work are controlled and when the operation concerns itself with the fewest possible sources of error.

The experience with blood transfusion of one of us (F. S.) extends over the last eleven years. At the beginning of the work, there were tried out and discarded all the transfusion methods that were concerned with blood altered from the state in which it flowed from the veins of donors. We felt that, difficult though the problem might be, in order to get all possible advantage from the procedure, one should endeavor to introduce nothing with the blood that was not a normal constituent of it. Therefore, all our transfusions have been made with whole blood. The medium of blood transference has been Percy's ingenious modification of the paraffined glass cylinder, orginally suggested by Kimpton. Thus, we have worked with errors reduced to a minimum and have secured results which are, at least, comparable. The variables still remain, as they will always, the bloods of the donors and the bloods of recipients as they may be biologically or chemically affected by various ailments.

DISCUSSION OF POST-TRANSFUSION RESPONSES

Harmful sequelae to blood transfusion have been manifested to us in three forms: (1) the acute and fulminant; (2) the delayed, not rarely, a disturbance acutely arising, and occasionally violent; (3) the systemic or constitutional, a malfunction, usually febrile, and associated with renal, cardiac, neurologic or gastro-intestinal phenomena.

1. *The Acute (Hemolytic) Recipient Response.*—Previous to the fundamental observations of Guthrie and Huck,[5] our donors were selected successively by the Rous-Turner, Moss, Brem-Moss and, lastly, the Vincent methods of typing. During the experimental period, more than 800 whole blood transfusions were performed by our colleagues and us. Since Guthrie and Huck's report on the limitations of the four group typing, we have selected donors, not only with respect to their positions in the Brem-Moss classes, but also on the basis of their agglutinin-agglutinogen content with prospective recipients (cross-grouping; direct matching). Fifty-four transfusions have been performed with this added donor control. It is a significant tribute to the work of Guthrie and Huck that we have seen no acute, hemolytic recipient responses since we adopted their procedure.

The acute reaction varies in severity directly with the volume of unsuited blood given, but there seem to be minor factors which aggravate the violence and duration of the response. The rate at which blood is introduced, the total time blood has been out of the donor before it is administered, the cooling of blood below 97 F., its exposure to air leading to thrombin formation, the physical blood alterations of preclotting character, and tissue or cell traumas conducive to platelet clumping and to microscopic clots, all appear to be causes capable of producing intense response. Our work indicates that incompatible blood given to a subject in good general shape but affected with an advanced, secondary anemia excites reaction of a degree far greater and more immediate in occurrence than when the recipient is ill from a primary blood dyscrasia or a disease of serious, organic nature. In the latter circumstance, it would seem that not only are protective serum substances deficient in their power to agglutinate and to break up foreign red cells and to split the introduced serum proteins, but liver, heart, kidneys and central nervous system are mechanically or physiologically limited in their capacity to take care of a large volume of cell suspension, suddenly introduced, or quickly to metabolize or eliminate a great quantity of toxic derivatives necessary to establish the pretransfusion balance of body fluids and of tissue function. Thus, it may occur that the foreign blood is successfully split, as would be any foreign protein introduced, but the outcome with respect to function or life lies in the physiologic integrity of those organs which have to do with the distribution, storage, ultimate cleavage and excretion of the alien substance. In the cachectic, or those whose vital tissues are damaged, the task imposed is often beyond the capacity of essential organs, and death is rapid.

It becomes plain, therefore, that the acute or hemolytic recipient response to blood transfused embraces two phases:

(*a*) In the first, the corpuscles of the introduced blood are rapidly agglutinated preliminary to their lysis. What changes follow in the donor's serum on this agglutination, we know little. Whether the donor serum mixes harmoniously with that of the recipient and then aids in the destruction of the agglutinated "foreign" cells or whether the donor cells, as they are agglutinated, disturb the colloidal balance of the donor serum and so render that serum just so much foreign material to be disposed of after the fashion of the cells, no definite statements can be made. The early and transient appearance of serum proteins in the urine subsequent to certain transfusions would appear to indicate that, in some instances, the donor serum-fraction of blood is excreted but slightly altered after the manner of egg albumin when administered intravascularly, or as are the serum albumins when fluid accumulates in serous sacs of the body. It is possible that donor serum may not crack the colloidal balance of the recipient's plasma, but may persist, unsplit, as a foreign serum and pass, unchanged or slightly modified, into the urine. This is in contrast to the mechanism for taking care of agglutinated blood cells. Some of these are engulfed by leukocytes or are directly cleaved. In either event, the fragmented cells constitute a mass of stroma, mineral, albumin and salts which demands active reduction, segregation, storage and elimination before the pretransfusion balance of the recipient's plasma is restored. The clinical phenomena exhibited as acute or hemolytic reaction are conservative and protective in nature, even though, in the working of this function, the result may be fatal or permanently damaging to the recipient.

The lytic crisis occurring after transfusion may prove quickly fatal. One of our early experiences included an instance in which death followed within ten minutes of a transfusion given as an emergency measure, when there had been opportunity for but limited donor selection and for blood typing of the crudest. The patient was actually drowned in his own fluids, as pulmonary transudate filled the alveoli. No form of therapy was of avail; the water logged heart returned no response to intravenous digitalis preparation in large dose; epinephrin, if it ever reached the capillary bed, excited no constrictor action. Further, our dosage of epinephrin to counteract post-transfusion reactions was much smaller at that time than is now given.

(*b*) The second phase of the acute recipient response to incompatible blood comprises a great variety of clinical, hematologic, chemical and pathologic abnormalities. If the fulminant phase has not caused death, subsequent disability depends on numerous factors. Of these, we would emphasize particularly the character of the ailment for the relief of which transfusion was performed; the volume of alien blood given, and the pretransfusion, functional efficiency of such organs as the liver, heart, kidneys, blood making tissue, central nervous system and the lungs.

It should be recognized that during the second phase of the acute lytic response the recipient is urgently confronted with the problem of mechanically accommodating a 20 per cent. increase in blood volume, of metabolizing or storing at least an equal percentage of cells (and, probably, serum split products), and of eliminating, by several avenues, a quantity of useless or harmful material suddenly acquired. To essential organs, the demands on physiologic reserves are immediate and extensive. Since, in health, we have only crude and inaccurate methods available for the determination of physiologic reserve, it is quite evident that, when a subject is affected with a dysfunction sufficiently serious to require blood transfusion, the question of functional reserve becomes vital. Death of normal human beings or of experimental animals from specific anaphylactic shock is not an uncommon happening. Such termination is proof of how quickly physiologic reserve may become exhausted. This analogy indicates the possibilities for embarrassment when organs, already damaged by disease or prolonged anemia, are called on to meet the emergency created by a foreign protein material equal to a fifth or a fourth of the subject's own blood proteins. The recipient may be well able to survive the acute vascular crisis associated with lysis, but later may succumb to the metabolic or eliminative load that burdens the kidneys, liver or central nervous system—organs that have been deficient in functional capacity previous to transfusion, and that are further handicapped by the capillary phenomena arising at the immediate transfusion response. Thus it follows that, during the desperate attempt to restore the pretransfusion balance (body fluid and tissue), one or more of the essential organic systems may cease wholly to function. Depending on which basic system fails earliest, the clinical and laboratory pictures of the events vary subsequent to the lytic crisis. So also, do the duration of life, the possibilities of ultimate recovery or the extent of permanent pathologic damage. The recipient may live a few hours or may remain alive but in desperate condition, as did one of our subjects, for as long as twenty-three days.

Before leaving the consideration of these recipient response phenomena, a late skin observation might be recorded. One of our patients, who lived rather more than three weeks subsequent to transfusion and lysis, exhibited huge urticarial wheals about eight days following the operation. These were very annoying on account of itching; they persisted several days. Their disappearance was followed by extensive skin exfoliation. The picture in all respects resembled that common to specific anaphylaxis, e. g., horse serum. We suggest that these dermal anomalies actually are anaphylactic and specific. Ashby[7] has shown that transfused blood cells may live as long as thirty days; their resistance increases with age, and when certain fractions of serum albumin bathe them. We consider that, even when incompatible blood is transfused, older cells are lysed with more difficulty than are younger cells. As Ashby has shown, in particular circumstances, agglutination may protect from ready hemolysis. It has appeared to us that the primary lysis of transfused blood, in the patient mentioned, was a destruction of younger red cells, or, at any rate, some cells escaped lysis. As time passed, the recipient's serum can be assumed to have developed its lytic ability for red cells to a degree even greater than that exhibited when the cells of the incompatible blood were first introduced. In such event, we regard the late skin changes as representing a lysis of older transfused cells or of such cells as escaped the immediate post-transfusion attack. This second manifestation of lysis represents an anaphylaxis; i. e., specific destruction of the red cells of the donor. We do not consider these phenomena an evidence of an autohemolysin, because there is no proof that the recipient had ever shown such characteristic dermal manifestations during his pretransfusion course; the phenomenon is only evidence of an autohemolysin in the sense that it arose and was exhibited after donor cells had been resident some days in the recipient's serum. This delayed, lytic manifestation assumes the character of anaphylaxis against the donor's cells, which, apparently, have been aroused as a sensitization phenomenon excited by alien red cell proteins accumulating after the first erythrocyte cleavage.

---

[7] Ashby, Winifred: Am. J. Physiol. 68: 239 (April), 250 (April), 585 (May), 611, 1924.

Hematologically, the acute lytic reactions are characterized by: delayed coagulation time; lower specific gravity of blood; fall in red cell count to a figure usually lower than pretransfusion count; drop in the leukocyte count, frequently from two to four thousand less than the pretransfusion white blood cell count (this in contrast to the effects on the blood of a successful transfusion, in which event the post-transfusion leukocyte count is usually from two to four times greater than it was before the transfusions); striking reduction in blood platelets; a lowered polynuclear ratio; an increased lymphocyte count, and the early appearance of nucleated cells. If the patient survives the acute lytic response, after twenty-four hours, the red cells begin to increase, the lymphocytes decrease, platelets reappear, clotting time is reduced, poikilocytosis is less marked, and, in the event that one is not dealing with an aplastic bone marrow, blast cells persist or appear. Particularly in the so-called pernicious or hemolytic anemia, in the past, have crises of blast cells been looked on as indicative of an early termination. However, our experience in the treatment of severe anemias by whole blood transfusion leads us to regard the appearance of blast cells following transfusion as a rather favorable omen; the presence of these cells at least indicates that we have to deal with a marrow still capable of red cell manufacture, rather than an aplastic marrow incapable of producing new red cells in an emergency. To be sure, these blast cells are not so functionally efficient as are matured corpuscles; but, in the circumstances, the partially functioning cell is better than no cell.

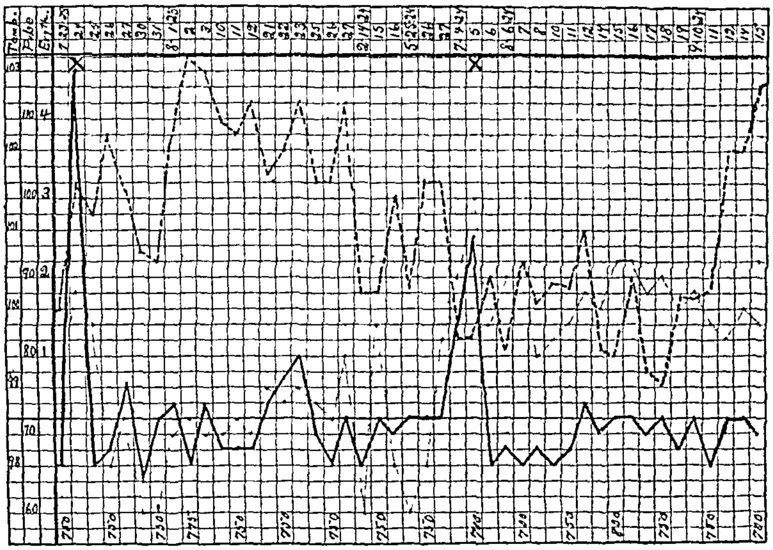

Fig. 2.—Constitutional response and red cell count variations occurring in association with a transfusion of whole blood in a case of hemolytic (Addison's) anemia when Moss Brem groupings were satisfactory but when cross-grouping had not been performed. The absence of reactions at the several other transfusions may be noted. Solid line, temperature; broken line, erythrocytes; dotted line, pulse.

While a successful transfusion is followed by less frequent heart rate, elevation in blood pressure and diminished clotting time, we have observed that, in instances in which the hemolytic crises occurred, there were increased heart rate, a rather sudden drop in blood pressure, lowered leukocyte count and prolonged clotting time. These anomalies occurred even when there was no immediate post-transfusion chill followed by temperature rise. They are most pronounced, however, when the hemolytic response follows immediately on the giving of blood. These post-transfusion phenonmena resemble the Widal crisis[8] of nonspecific shock observed when the barrier of proteopexic function of the liver is lacking or reduced.

2. *Delayed Recipient Responses to Transfusion.*—In this group we class such reactions as do not follow immediately, or within a few minutes after, introduction of donor's blood. This type of response usually appears within from one to four hours after the transfusion. Obviously, the mechanism of this reaction differs from the lytic crisis occurring during or closely related to transfusion. It is difficult to conceive of a condition in which the unsuited blood circulates for more than an hour, and yet, if the mechanism of response is similar to that of our Class 1, the donor's red blood cells are carried about in agglutinated form and yet not broken up. It is an undisputed fact, however, that as much as a thousand cubic centimeters of blood seemingly typed correctly may, in certain instances, be given, the operation finished, the patient apparently greatly benefited, and then this favorable outcome be reversed without warning. The subject then passes through experiences in every way comparable to those observed in the acute "hemolytic" crisis. The following case illustrates the leading features of this delayed response:

A man, aged 59, affected with hemolytic (pernicious) anemia, of Group 4 (Moss-Brem classification), with a temperature of 98.6, pulse 92, respiration 14, was given 750 c.c. from a Group 4 donor, not tested for agglutinin or agglutinogen by cross-grouping. The transfusion was in every way satisfactory until an hour following the operation, when there were sudden, severe rigor and exhausting chills, each chill lasting about thirty minutes; there was no backache or dyspnea, but considerable nausea and great prostration. About two hours following the transfusion, the patient's respiration was 14, pulse 84, temperature 103; there was no blood-derived pigment in the urine. Erythrocytes before the transfusion were 1,064,000; leukocytes, 6,200; after transfusion, erythrocytes, 2,450,000. The condition persisted for several hours; the temperature then fell by lysis during two days; nausea and weakness disappeared, and the white cell count approached pretransfusion figures. Three weeks later, a laparotomy was performed, at which time the gallbladder, appendix and spleen were removed. Our subsequent transfusions were followed by no untoward responses, and the patient rapidly gained strength and vigor. A year later, the erythrocytes numbered 1,200,000; the patient was extremely weak; his heart dilated; there were blood-derived pigments in the urine; constant nausea; albumin and casts in the urine, and the urine output was scant. A Group 4 donor was cross-grouped with the recipient's blood. The cross grouping showed a very slight degree of agglutination of the patient's cells by the donor's serum, but in the emergency, this blood had to be used; 700 c.c. was given. Approximately one hour after what had seemed to be a successful transfusion, a severe chill occurred; it lasted twenty-five minutes and was followed by temperature rise to 100, respirations of 20. No blood-derived pigments appeared in the urine; the erythrocyte count eighteen hours after transfusion was 2,100,000; the general condition was markedly improved. Without further reaction, six transfusions were subsequently given (Chart 2).

---

[8] Brown, T. R.: Ann. Clin. Med. 1:380, 1922.

Analysis of this case (typical for the group) demonstrates that the so-called delayed "reaction" is not a hemolytic process, even though, roughly, it resembles such and often is so considered. It differs from a lytic crisis in that the erythrocytes are definitely increased by transfusion and the increase is maintained; blood-derived pigments are not found in the urine; clotting time is not delayed; heart rate is reduced; no petechiae, purpura or oozing from mucous surfaces is observed, and the patient experiences the well-being common to successful blood transfusions after the first twelve hours have passed.

While this recipient's response varies definitely from that due to acute hemolysis, it resembles the manifestation when a foreign protein, as horse serum or other alien albumin, is administered to an individual sensitized to it. Several explanations may be advanced for this type of reaction. It commonly occurs in individuals who harbor bacterial foci (in the biliary tract, lung tissue, wall of the intestine, etc.). In such circumstances, we have considered that these delayed responses represented bacterial cleavage or protein cleavage of damaged tissue at a bacterial focus, caused by the donor's blood increasing the protective, bacteriolytic or protein cleavage power of the recipient's serum. In this event, the reaction appears to be a manifestation of parenteral protein splitting. That something of this nature occurs is demonstrated by rapid healing of the injured tissue or of visible surface foci of infection (varicose ulcers, boils, etc.) following transfusion. Variation in time of appearance of the recipient's delayed response (from one to twelve hours) would seem to indicate that the rate at which bacterolytic or protein cleaving agents accumulate in the blood and of strength to split different strains of bacteria is not fixed. Bacteria may vary in their resistance according to their type, number and locations of growth. If the recipient's serum, previous to receiving fresh normal donor's serum, already contained bacterial lysins, but not of sufficient degree to lyse a considerable number of bacteria, then the addition of a strong lysin, by transfusion, would render effective the combined serums in the recipient more quickly than when a strong donor's serum was added to a recipient serum that was already exhausted by a previous exertion of its lytic power against long established bacterial colonies.

Another explanation of these delayed responses may lie in the fact that, while the combined donor and recipient serum is capable of splitting foreign proteins, such split-products are, in the event that the recipient has normal protopexic liver function, filtered by the liver and do not pass, as partly split protein, to the vascular tree beyond the liver. These split products are disposed of in the normal way. However, should the liver's protopexic function be below normal, the leakage through of various kinds of partly altered protein then results in parenteral cleavage and there occurs nonspecific protein shock (Widal crisis). It would seem possible that the factors of increased bacteriolytic power in the recipient's serum and of deficient liver barrier function may both be present. Certainly, the reaction points to protein cleavage rather than to hemolysis, as shown in the accompanying table.

It was stated that, in the patient cited, the donor's serum slightly agglutinated the cells of the recipient. One might conceive of a condition in which this weak agglutination process gradually took place following the transfusion, and that a subsequent reaction was a cellular lysis. In such event, however, it is difficult to explain why such cell lysis was not followed by the appearance of blood-derived pigments in the urine, in the duodenal extracts or about the peripheral capillaries. Moreover, in this type of reaction, increase in the red cell count following transfusion is maintained, and capillary embarrassment with transudation or purpura is lacking. The patient has no abnormal peripheral sensations or cerebrospinal manifestations. He does well clinically. Indeed, in some instances, this type of reaction seems necessary before the patient regains strength and vigor. From experience, we have come to regard these delayed reactions as conservation phenomena; in special instances, we look for them with the expectation that, after they have occurred, the patient will make a more rapid recovery. In two cases of marked anemia, due to sepsis following abortion, the first three transfusions were followed by delayed reaction of the type described. The subjects improved progressively with each transfusion, despite the shock. Following the fourth transfusion, no untoward symptoms appeared and both patients progressed to an uninterrupted and complete recovery.

However, these delayed recipient responses may be productive of serious consequences. If, previous to the transfusion, there were already present renal insufficiency, cardiac dilatation and myocardial degeneration, with low diastolic blood pressure or alimentary tract disturbances, the shock of the delayed response, together with the necessity for the elimination of toxic by-products of protein cleavage, may lead to fatal termination by exhaustion, heart embarrassment (seemingly of central origin) or to an uremia-like syndrome. One of our patients well illustrates this:

> Three whole blood transfusions, at five-day intervals, were in every way successful, and increased the patient's red cell count from 799,000 to 3,900,000. Each successful transfusion was accompanied by increasing tenderness about the gallbladder and bile ducts, and by slight diarrhea. The renal output was maintained, blood-derived pigment never found, but all specimens exhibited albumin and casts. A fourth transfusion produced what appeared to be marked irritative biliary tract signs accompanied by a scanty urine output, albumin and casts being excessive. Within eight hours following the transfusion, the temperature rose, pulmonary and localized cerebral edema appeared, with delirium; death occurred as the result of urine suppression and respiratory distress seemingly of bulbar type.

Summary of Data Concerned with Four Reactions Subsequent to Transfusion of Whole Blood

					Before Transfusion			After Transfusion				Before Transfusion		After Transfusion	
Diagnosis	Age	Previous Transfusions	Group	Group of Donor	Temp.	Pulse	Resp.	Temp.	Pulse	Resp.	Amount Transfused, C.c.	Erythrocytes	Leukocytes	Erythrocytes	Leukocytes
1. Hemolytic anemia..........	59	0	4	4	98.6	92	14	103	84	20	750	1,640,000	6,200	2,450.000	5.500
2. Hemolytic anemia..........	..	9	4	4	98	90	20	100	94	20	700	1,200,000	......	2,100,000	......
3. Hemolytic anemia..........	45	4	4	4	100	92	28	101.6	120	36	700	2,130,000	19,450	3,150,000	16,500
4. Chronic diffuse nephritis....	64	2	4	4	98	70	18	99.6	70	18	750	4,000,000	7,000	5,000,000	5,100

At no time did this patient exhibit icteroid coloring or blood-derived pigment in the urine or stools. Here, transfusion was successful as a procedure, but the renal elimination of toxic products and the effect of these toxic products in the capillary circulation led to death at a time when the outcome seemed bright.

3. *The "Constitutional" Recipient Response.*—If carefully observed, practically all transfusions are accompanied by a febrile rise of varying degree. The temperature ranges from 100 to as high at 105. The rise occurs within three hours following transfusion and may be maintained for as long as three days. Apart from fever, the patient has no particular discomfort, nor does he exhibit signs suggesting blood destruction even of slow but constant degree. In a patient, who previous to transfusion has no cardiovascular-renal, cord or organic alimentary tract dysfunction, such constitutional reaction has relatively little significance.

Its mechanism is difficult to explain. In the absence of evidences of blood destruction, we have felt that the recipient's responses were caused by bacterial lysis, by the splitting up of some unassimilable serum protein or protein derived from the site of unobtrusive, but nevertheless present points where there was damaged tissue. Only rarely, in this form of reaction, have we found blood-derived pigments in the urine or feces. The red cell count is well maintained. If such reaction occurs, however, in a patient who has liver, kidney or heart damage, in which condition there may be low functional reserve, the transfusion directly may precipitate embarrassment in vital organs and be accompanied by death or at least long continued illness.

We would emphasize the necessity for carefully observing for from two to four days these patients in whom the blood transfusion has seemed successful. If careful observation is carried on, the sudden and unexpected appearance of heart, kidney, liver or respiratory embarrassment will not occur. General and medicinal measures may be instituted before a uremic state or heart failure appears. When evidences of lowered capacity of essential organs is present, further transfusion should be postponed until conditions have approached normal. Certainly, in this type of case, further transfusion should be interdicted so long as the patient is febrile, has nausea and vomiting, is difficult to feed or has the products of blood destruction appearing in definite or increasing quantity in his urine. If transfusion is performed in the face of these cautions, whatever chance of recovery the patient may have had is likely to disappear.

MEANS BY WHICH HARMFUL POST-TRANSFUSION SEQUELAE MAY BE AVOIDED

(*a*) *Blood Typing.*—Our experience emphasizes the necessity for cross grouping of recipient's and donor's blood if one is to avoid the acute or the delayed post-transfusion reactions. We are fully in accord with the observation of Guthrie and Huck. While the four-group classifications of Moss and Brem may prove clinically reliable in the majority of transfusions, yet one can never feel confident that bloods typed by such a method can be mixed safely. Particularly when patients have been transfused frequently, and numerous donors have been employed, is it necessary to regroup bloods at every transfusion, and in all instances to cross-group the blood. The four post-transfusion reactions (Fig. 3) occurred in a series of 106 transfusions recently performed by one of us (R. A. K.). All of these reactions occurred before we adopted cross-grouping of donor's and recipient's blood as a routine, and supplementary to typing by Vincent's microscopic method. A later series of fifty-four transfusions in which bloods were cross-grouped was followed by no reaction.[9]

Certainly, selecting donors without cross grouping makes blood transfusions a hazardous clinical procedure. Unquestionably, many of the untoward sequelae of transfusions reported in the literature have been due to clinicians having placed too much reliance on the four-group method of typing. It is these unfortunate transfusion sequelae that have caused blood transfusion to fall into disrepute in certain quarters.

(*b*) *Whole Blood Versus Citrated or Otherwise Altered Blood.*—There seems to be no reason why, if proper apparatus and sufficient technical skill are at hand, anything but whole blood should be employed in transfusion. The plea of expediency and speed should be no excuse for the uses of blood altered by the addition of various salt solutions. If transfusion is really needed to insure clinical benefit to a patient, blood in its most efficient biologic form should be employed and the operation of transfusion should be carried on with the greatest care. Here is not the place to discuss the various forms of mechanical aids to transfusion or to quote statistics showing the advantages of whole blood over citrated or otherwise altered blood. We have already stated above why statistical comparisons in blood transfusions are of little value. Certainly, our experience indicates that the use of whole blood, properly typed, insures fewer post-transfusion reactions and greater clinical benefit than by the employment of citrated, salted or blood otherwise changed. Less than 4 per cent. of reactions of any kind have followed the use of whole blood.

(*c*) *Anaphylaxis and Protein Shock.*—These terms have been employed loosely with regard to post-transfusion reaction. We have already emphasized some of the possibilities for confusion. Many of the so-called "anaphylactic reactions" accompanying blood transfusions are really protein shock, i. e., due to nonspecific protein, and in such event no previous sensitization is necessary. Anaphylaxis was not observed in any of the four post-transfusion reactions occurring in our last 106 transfusions. Several of the patients in this series have received from ten to sixteen transfusions. Passive anaphylaxis[10] may be avoided by questioning and examining the prospective donor for the transfusion. Ramirez[11] records an instance in which positive sensitization to horse hair protein occurred following donation of an asthmatic's blood. In our four post-transfusion reaction there was a diminution in leukocyte count, a clinical phenomenon highly suggestive of Widal crisis. Such phenomena emphasize the necessity for considering certain reactions as being possible when the diminished proteopexic liver function permits leakage of circulating proteins through the liver, with subsequent parenteral cleavages of such proteins.

---

[9] A very simple method of cross grouping that we have found practical is as follows: About 1 c.c. of blood is withdrawn by means of a fine needle from a vein of the donor and recipient, and each added to an equal amount of physiologic sodium chlorid solution to which a few crystals of sodium citrate have been added. These are centrifugalized. The supernatant fluid is then withdrawn by a pipet into other containers and each labeled. Two or three drops of this supernatant fluid is placed on one glass slide. To this is added, by means of a platinum loop, a loopful of the cells of the patient's blood. These are agitated by the platinum loop to mix the two thoroughly. Then to a few drops of the patient's serum is added, in a similar way, cells of the donor. If agglutination takes place at all, it usually is within a minute (Fig. 3). Warming the slide to body temperature will hasten any possible agglutination. The cells are then examined microscopically. We have very frequently noted agglutination, in instances in which the blood of both the patient and the prospective donor were separately typed as Type 4.

(*d*) *Pigmy Transfusion.*—If an ailment or an accident calls for blood transfusion as an emergency measure and test serums are not available or are dubiously reliable, serious immediate or delayed post-transfusion responses may be avoided by intravenous or intracutaneous injection of small blood volumes taken from prospective donors.

Following the intravenous introduction of from 15 to 30 c.c. of incompatible whole blood, the subject exhibits mild sensations of peripheral skin discomfort, is restless, may be somewhat dyspneic, has slight chill, and may perspire locally about the forehead or feet, or in the axillae or palms of the hands. Temperature observations disclose elevations of from 1 to 3 degrees F., the rise being rapid, the fall by lysis within six hours. Nausea and, rarely, vomiting may occur. The inconvenience is not great, however, and the response is so acute that such pigmy transfusion is of practical value and its employment is justified. In instances of severe blood dyscrasia, when numerous transfusions have been made previously or in advanced cachexia, the responses to pigmy transfusion of whole, incompatible blood, whether it be introduced into areolar tissue or into the veins, the local or systemic "reactions" are apt to be not so pronounced as when the test is given to subjects who are affected with secondary anemia. This applies, even though in each group of patients, the blood counts are closely approximate.

(*c*) *Indications.*—Blood transfusions should be made with extreme caution and only in dire emergencies when subjects exhibit pulmonary or cerebral edema; when the renal output is low, and the urines contain albumin, casts or blood; when deficient cardiac strength has resulted in persistent peripheral edema, or where myocardial weakness admits but little added stress. In such instances, the transfusion of compatible blood may precipitate an acute, fatal crisis; the use of incompatible blood is commonly followed by cerebral, cardiac or renal failure, or rapidly increasing pulmonary edema literally drowns the patient. Post-transfusion and visceral edema may lead to exhausting diarrhea or vomiting; not rarely this has been considered central in origin. It is difficult or impossible to control. Certainly, previous to blood transfusion—whether whole or modified blood is used—the efficiency of the heart and kidneys should be determined and careful physical examination should exclude cerebral, pulmonary or splanchnic zone edema. If the examinations disclose any of these dysfunctions, then transfusion should be postponed until, by rest, diet or medicinal agents, the situation has changed. When untoward post-transfusion phenomena appear (tight skin sensations, restlessness, air hunger, pink flush to body surface, cough, etc.), knowledge that the physiologic upset attacks first the circulation at its capillary bed, demands the prompt exhibition of epinephrin. Fifteen to thirty drops of the 1 : 1,000 solution, diluted with 30 c.c. of physiologic sodium chlorid solution, should be given slowly into a large vein. The embarrassed condition of the capillary bed contraindicates small doses of epinephrin administered subcutaneously or intramuscularly; such are not effective anywhere but locally, at the injection site. The epinephrin solutions may be given as frequently as at half hour intervals, depending on their action. It is our opinion that, as knowledge of the vascular crisis in the acute post-transfusion reaction has been previously indefinite, the dosage of epinephrin has been too small to be effective. Digitalis and other heart stimulants are usually not useful (although they are employed quite generally) unless epinephrin is also given. When it appears that the acute distress has passed, then blood clotting is aided by intravenous injection of from 10 to 20 c.c. of 1 per cent. calcium chlorid solution as frequently as every four hours for at least six injections. Within twelve hours following the transfusion reaction, stimulation of renal function should be attempted by the intravenous exhibition of 10 grains (0.65 gm.) of caffein sodium benzoate at six hour intervals, or, if there is no gastric upset and nourishment is being taken without nausea or vomiting, 15 grains (1 gm.) of theobromin sodiosalicylate every eight hours. Fluids should be given by mouth in moderation; too often they are pushed in the endeavor to wash out an accumulation of toxic products of hemolysis. This is an error: the reaction has already rendered peripheral tissues very edematous; the blood is more than ordinarily fluid and its clotting time prolonged. The object of diuretics should be to stimulate an edematous kidney first, to free itself of its own fluid excess, and then to excrete the increased tissue edema so generally present in this acute vascular crisis. Pushing fluids only throws an added burden on kidneys already seriously taxed.

SUMMARY

1. If whole blood is employed in blood transfusion and if donor blood is carefully selected, post-transfusion reactions are relatively rare: less than 4 per cent. in our series.
2. Post-transfusion effects of a harmful type may be minimized if donors are selected not only with respect to their place in the arbitrary four group classification of Moss, but when donor and recipient bloods are cross-grouped for estimation of their agglutinin-agglutinogen content.
3. There are three types of post-transfusion: the immediate or hemolytic, the delayed, apparently not hemolytic but proteolytic, and the constitutional or nonhemolytic.
4. The subjective and objective phenomena of hemolysis can be explained by the effects of lysed blood on the peripheral capillary bed. The mechanism of this capillary response is similar in kind, but greater in intensity, to peripheral vascular phenomena observed in Raynaud's disease, purpura, etc.
5. The nonfulminant and delayed post-transfusion reactions are caused by anaphylactoid protein phenomena, but not necessarily of specific nature.

1002 North Dearborn Street.

ABSTRACT OF DISCUSSION

DR. F. W. HARTMAN, Detroit: We would suggest an additional group in the types of reactions mentioned by Dr. Smithies; that is, atypical anaphylactic attack with swelling of the face, cyanosis and difficulty in breathing during the transfusion or within a five minute period following transfusion. We have seen such a reaction four times in a series of approximately 300 cases, and it is almost immediately relieved by the administration of epinephrin. The hemolytic reaction should no longer, we believe, be considered when speaking of blood transfusion reaction, since the usual typing of the blood and cross agglutination of the patient's and donor's blood will eliminate the possibility of this occurring. All other types of reaction, occurring within a one hour to three hour period after transfusion, should be grouped together, since they are probably manifestations of the same factor or factors, whatever this may be. It seems that these factors are definitely associated with the transfused blood coming in contact with foreign material. In this connection we recall the work of Novy, who showed that blood withdrawn from a guinea-pig and allowed to come in contact with inert foreign substances and again injected often produced a fatal shock. In using citrated blood there are two other possible factors; namely, the citrate itself and the water with which it is made up. Huntoon has shown how important the water factor is in his work on pneumococcus antibody solution. A factor that has seemed of some importance is the marked rouleau formation which we sometimes see in cross agglutination. We have felt for several years that this was possibly a type of incompatibility, and, by eliminating donors which show this rouleau formation with the patient's blood, we have been able to cut our reactions with the citrate method to about 10 per cent. In a personal communication, Dr. Longmire of Texas tells me that in a series of 150 cases done with the citrate method, taking this precaution about rouleau formation, he has not had a single case showing chills. The shock occasionally associated with the rapid administration of a direct transfusion should not be included as a transfusion reaction but should be kept in mind. We recently saw a patient with mitral and tricuspid stenosis who died with acute pulmonary edema within the twenty-four hour period following such a rapid direct transfusion. With citrate transfusions, such shocks may be avoided by using a small needle and spreading the administration of the first 100 c.c. over a longer period of time.

Dr. Henry F. Stoll, Hartford, Conn.: A factor that has not been mentioned is the use of apparatus that is not perfectly clean. Repeatedly, after apparatus has been given me as ready for use, on further rinsing with ether, a considerable amount of foreign material (dried blood) has been obtained. Unclean apparatus unquestionably contributes to reactions that, while not of the serious type, are, nevertheless, very unpleasant for the patient. In regard to avoiding the immediate reactions, due to improperly matched bloods (and incidentally the man doing the transfusion should either perform his own blood matching or confirm the grouping), if the first 20 c.c. of blood is injected very slowly, as can be done if a little 2 per cent. citrate or physiologic sodium chlorid solution (5 c.c.) is added to the first syringeful, the early signs of incompatibility are immediately recognized and the injection is stopped before harm is done. The rapid introduction of a large amount of blood is always accompanied with some hazards. Chemically pure citrate made with freshly distilled water can be excluded as a cause of reactions. I have injected a buffered solution of sodium citrate that has a p_H value of 7.6 or 7.8 for the relief of pain of thromboangitis obliterations upward of 200 times, and I have never yet had a single reaction although more citrate is given than in an ordinary transfusion. Dr. Stokes at the Mayo Clinic showed that certain brands of rubber tubing contained toxic properties when new unless they were soaked in a solution of sodium hydroxid before use. The direct (syringe-cannula) method gives fewer reactions than the citrate method, but it isn't the citrate as much as it is the manipulation and chilling of the blood and the use of improperly cleaned apparatus.

Dr. Andrew A. Eggston, New York: I believe that the one who does the transfusion should be responsible for the typing of the bloods. The typing serums, unless frequently controlled and properly preserved, may be a source of error. I always preserve the type serum in sterilized and sealed vaccine ampules. In this way they will keep almost indefinitely. A new ampule is opened each time a typing is done. Cross typing is always done before a transfusion. I do not think that rouleau formation of the red cells, spoken of by one of the previous speakers, has very much relation to the reaction. Rouleau formation to a certain extent depends on the solution in which the red cells are suspended for the typing. If blood is collected in a citrate solution, rouleau formation is more frequent than in a physiologic sodium chlorid solution. I have used donors who have shown rather marked rouleau formation on cross typing, with no distinct harmful reaction. Outside the very serious reactions that occur in transfusions, the temperature reaction may be overlooked as they have therapeutic value, particularly in infectious cases. Nonspecific proteins are used in many infections to produce reactions in the treatment, with good results. Therefore they may be minimized following transfusions, particularly when only a mild elevation of temperature occurs for a few days. The very severe reaction should be avoided, if possible. No doubt certain physical conditions of the recipient are likely to account for some serious reactions. I refer to pulmonary edema in cases of fatty degeneration of the heart that occurs in pernicious anemia. Likewise, in chronic nephritis, transfusion should be done with great caution. In considering the method of transfusion, experience is a determining factor. Formerly we used the citrate method, but now we use a direct method. In all, we have done between 700 and 800 transfusions. The direct method is certainly a much nicer technic and distinctly more surgical. The blood must be delivered very quickly, and a great deal more time and skill are required to master the technic. On the other hand, the citrate method should not be condemned altogether because there are many localities where physicians do not perform enough transfusions to master the technic of the direct transfusion, and the citrate method is certainly a good substitute.

Dr. Martin L. Janes, New York: Two points must be considered in every transfusion so far as its successful outcome is concerned; that is, first, the proper grouping by the person who is to do the transfusion. That person's mind and judgment should be trained to form conclusions regarding the proper matching that is done on the slide or under the microscope. The second major point in the technic of the performance of a blood transfusion. There is no question of the fact that physiologic sodium chlorid or citrate solutions do contribute to the possibility of post-transfusion reactions. The ideal method of transfusion, without any doubt, is one that transfers the blood as rapidly as possible without the introduction of any foreign material whatever. It was with this idea in mind that, about five years ago, I presented an apparatus in which two syringes were employed, one filling while the other one discharged, and vice versa, so that there was a continuous flow of blood provided between the donor and recipient, without the necessity for the introduction of any foreign material. In a series of 260 consecutive cases of blood transfusion that I have performed since in various hospitals in New York, I have had not a single reaction, and the only reason for these results is the fact that I have personally supervised the matching of the bloods and also because of the smooth technic in the transference of the blood. An ideal method of transfusion is one that transfers the blood rapidly with the least exposure of the blood to any extraneous material and the least amount of time in which that blood remains outside the blood vessels.

Strabismus Among School Children.—In the course of some 12,000 examinations of school children of all ages in Nassau County, N. Y., New Castle County, Del., Porter County, Ind., Frederick County, Md., and Spartanburg and nearby mill villages in South Carolina, made by officers of the U. S. Public Health Service, 0.9 per cent. were observed as having strabismus. About four fifths were internal and one fifth external in type. The strabismus rate for girls is slightly higher than for boys when all ages are considered together. The percentage of children who have external strabismus is practically constant throughout the school ages, showing possibly a slight tendency to increase. On the other hand, internal strabismus is much more prevalent among children under 12 years than it is among older children. At Gary, Ind., the strabismus rate was 1.3 per cent. among 994 children under 2 years of age, and 2.4 per cent. among 3,125 children from 2 to 7 years of age. The association of strabismus with diminished visual acuity is quite definite. The rates increase regularly from 0.13 per cent. for children with normal visual acuity to 8.11 per cent. for those with vision of 20/70 or worse in one or both eyes. The difference between these rates, 7.98 ± 2.14, is significant, being more than three and one-half times its probable error. Of more importance, perhaps, is the fact that the increase in the strabismus rate as visual acuity decreases is regular for both boys and girls. The percentage of children who have strabismus increases as visual acuity decreases, even among the children who have approximately the same acuity in the two eyes.—Collins, S. D.: *Pub. Health Rep.* **40**:1516 (July 17) 1925.

UMBILICAL HEMORRHAGE ACCOMPANIED BY DEEP JAUNDICE

REPORT OF A CASE IN A BABY, AGED TWENTY DAYS

HONORIA ACOSTA-SISON, M.D.
MANILA, P. I.

This case is reported because the cause of the hemorrhage and jaundice could not be ascertained, and because the results of blood transfusion and roentgen irradiation were of interest.

Clinical Course.—Baby G., a boy, born spontaneously at the private maternity department, Philippine General Hospital, Dec. 28, 1924, weighed approximately 7½ pounds (3.4 kg.) and presented nothing unusual except a large, thick cord which the nurse was obliged to tie with three tapes. The infant nursed well and the mother had plenty of milk. On the second day, he became yellowish. On the fifth day, white spots appeared on the tongue and the buccal mucous membrane, and blisters, filled with yellow serum, appeared on the buttocks and upper parts of the thighs. The urine also became yellow. There was no fever. The blisters healed after treatment for one week with zinc oxid ointment and powder. The cord fell off on the twelfth day, leaving the umbilicus dry and well healed. The white coating of the tongue, common among the babies born in this ward, was removed daily by the nurse with cotton or gauze wet in weak potassium chlorate solution. After three days the mouth, tongue and lips became livid. Occasionally after nursing the baby ejected about one teaspoonful of red-tinged milk. The raw appearance of the mouth was attributed to too vigorous cleansing.

The child seemed to be normal except for the jaundice, yellow urine and red mouth. On the nineteenth day, however, the baby lost his voice. Efforts to make him cry caused only a grimace, without sound. The previous night the mother could not make him nurse; at midnight he had uttered a sharp cry, after which he slept and could not be awakened. Believing the child to be suffering from infantile beriberi (the mother was weak and anemic), I gave him tiquitiqui extract[1] hypodermically and by mouth.

The next day, the twentieth day of life, the cord dressing was found to be slightly stained with blood—the first stain seen since the cord fell off—and a dark blue spot formed on the left arm. Epinephrin solution, applied to the umbilicus, stopped the bleeding. The following day, the cord dressing was again stained with blood. The baby was given, intramuscularly, 5 c.c. of horse serum with 2 drops of epinephrin. However, big dark blue patches formed on the back of the chest. The cord dressing was changed daily and the blood stain increased more and more until the night of January 11, the twenty-fourth day since birth, when the bleeding from the umbilicus was profuse and could not be controlled by pressure, epinephrin, ferric chlorid or silver nitrate.

For want of surgical facilities in the patient's home, I controlled the alarming hemorrhage by clamping the umbilicus together with the surrounding skin. About one hour later, one tube of a proprietary hemostatic horse serum preparation was injected intramuscularly.

The next morning, the spleen and the long bones of the lower extremities were exposed to roentgen irradiation (from 75,000 to 80,000 volts) for one minute at a distance of 6 feet by Dr. Fernandez of the roentgen-ray department, Philippine General Hospital. Ten cubic centimeters of whole compatible human blood was injected intramuscularly, and, in the afternoon, Dr. J. Estrada injected in the median basilic vein, by the open method, about 75 c.c. of citrated blood. The effect of the transfusion on the color and appearance of the baby was marked. The roentgen-ray treatment of the long bones of the upper extremities was resumed five days after the first exposure. After the blood transfusion the baby was given, intramuscularly, every day for one week, from 8 to 15 c.c. of whole human blood. During this time, new dark blue blotches developed on the legs, the back of the hands, and the dorsum of the feet. The old patches became resorbed. The jaundice persisted, and bile pigments were found in the urine. The stools were regular and of normal yellow color.

Twelve hours after its application, the clamp on the umbilicus, which was long and cumbersome, was removed. Blood gushed out in the short interval until a shorter clamp could be applied. Two days after the application of the clamp, the surrounding skin became red and swollen. Dressings wet with hot aluminum acetate solution were applied. The inflammation was much improved the next day, but the clamp became rusty and was taken off, and a ligature of tape was substituted. The skin at the site of the clamp broke off and showed slight oozing of blood partially controllable by the application of ferric chlorid. The stump was black and gangrenous.

On the seventh day after the blood transfusion, the bleeding around the stump was so free that a purse-string linen suture was tied around the umbilicus. This controlled the bleeding. The stump had already sloughed up. The next day, the eighth day since the first blood transfusion, 120 c.c. of citrated blood was injected in the median basilic vein by Dr. Estrada. Two days after the application of the purse-string suture, the skin within the ligature came off, leaving a raw surface which was not bleeding. However, on the fourth day after the second transfusion, the bleeding from the raw surface was somewhat profuse so that 150 c.c. of citrated blood was injected in the saphenous vein, and bleeding from the umbilicus ceased.

On the fourth day after the third transfusion, the umbilicus began to bleed again. The stools and the secretion from the mouth were tinged with blood. The jaundice became deeper. Fresh cephalin, especially prepared by the Bureau of Science, was applied over the umbilicus, and partially controlled the oozing. The next day, serum from an eclamptic patient was applied locally and proved a more efficient styptic than cephalin. A daily intramuscular injection of 5 c.c. of Witte's peptone was begun on the same day. However, the tendency of the umbilicus to bleed increased daily, and neither the cephalin nor the serum from an eclamptic patient controlled the continuous oozing. On the eighth day after the last transfusion, 200 c.c. of citrated blood was injected in the other saphenous vein. The umbilicus had healed rapidly so that the raw surface, which had been bigger than a silver dollar, was reduced to the size of a quarter. Again, Dr. Castillo irradiated the spleen for five minutes and the long bones for four minutes, using 90,000 volts at a distance of 8 inches.

Much hope was entertained for the child's cure, but again on the fourth day after the last transfusion, the umbilicus, which was almost completely healed, resumed bleeding. At the same time, the right thigh at the site of the intramuscular injection of blood, made seventeen days previously, became swollen and red, denoting the development of suppuration. On the seventh day after the last transfusion, the baby became restless and uttered shrill, piercing cries, which were thought to be due to the condition of the thigh. Dr. Estrada removed about 20 c.c. of blood and later 10 c.c. of pus by aspiration. Within a few minutes, the right knee became swollen and black and the transfusion wounds of both thighs and one of the arms showed bleeding. The umbilicus had more active oozing, which could not be stopped by either cephalin or blood serum; but the site that bled the most and which was beyond control was the site of puncture of the aspirating needle. A few hours after the aspiration, the baby again uttered shrill, piercing cries. An internist who heard the cry suspected it to be of cephalic origin caused, probably, by hemorrhage in the brain or meninges. In less than twenty-two hours after the puncture of the abscess, the child died of exsanguination at the age of 1 month and 22 days.

Family History.—The mother and her family give no history of hemophilia. The father, a sister and a brother of the baby are bleeders. The father has occasional nosebleeds. The eldest brother, after the extraction of a tooth, had a hemorrhage that endangered life. One sister developed black and blue spots on the skin after slight trauma. The father had a negative Wassermann reaction.

---

[1] A local name for extract of rice polishings.

COMMENT

The jaundice appeared soon after birth and gradually grew in intensity until death. The urine and the serum under the blebs were deep yellow, an indication of hemolysis. No improvement was noticed as a result of the roentgen-ray treatment. The coagulation time and platelet count were not determined, but blood that had oozed out and had been undisturbed for more than seven hours was found to be liquid. After each transfusion, bleeding of the umbilicus practically stopped; but at the end of from four to five days, the bleeding recurred. Finally, diffuse bleeding from the mucous membranes of the mouth and intestines occurred.

DIAGNOSIS

The intense jaundice of the skin suggested the possibility of an obstruction in the bile ducts, but the stools were of normal color. In hemorrhage of the new-born, the bleeding occurs early, usually in the first week, and there is no history of bleeding in the family. Since the bleeding occurred in the first month, the coagulation time was much delayed, and since the disease appeared to be inherited, hemophilia was strongly suggested to us. However, hemophilia is a hereditary blood dyscrasia manifested by members of the male sex but transmitted only by the female members. The bleeders in the family of this infant were on the father's, not the mother's, side of the family. In purpura hemorrhagica the coagulation time is normal. In icterus gravis as described by Pfannenstiel,[2] there is "early jaundice increasing in intensity, absence of fever, presence of bile pigment in the urine, normal appetite, disposition to screaming and absence of acholia in the stools" and a tendency to umbilical hemorrhage. All of these symptoms fit the manifestations of our case.

ETIOLOGY

My impression is that the hemorrhages and the blebs were independent. In the maternity ward where this baby was born, a large percentage of the babies became affected with this pemphigus-like eruption, but no other infant had any complication nor did any of the infants, including our patient, have fever. The eruption in every case yielded easily to treatment with zinc oxid. The bleeding commenced eight days after the blebs had become entirely healed and dried up.

The father's Wassermann reaction was negative, and the obstetric history of the mother presents no indication of syphilis.

TREATMENT

The benefit of the first transfusion was marked, but the transfusion was effective only from four to five days. It is known that the life of the platelets is from three to five days. It is presumed that, at each transfusion, enough sound platelets were introduced to establish sufficient prothrombin to make the blood normal; but as soon as the foreign platelets died the old tendency to bleed returned. If this observation is correct, the proper treatment would be to try to enable the patient to manufacture prothrombin of normal quality and quantity, or if the cause be infective agents that destroy the normal prothrombin, to eradicate this factor.

The roentgen rays are believed to stimulate the blood centers, such as the spleen and bone marrow, and to increase the coagulation of the blood, but, to our disappointment, in this case irradiation did not bring about the desired result.

RECURRENT DISLOCATION OF THE SHOULDER JOINT [*]

T. TURNER THOMAS, M.D.
PHILADELPHIA

Recurrent dislocation of the shoulder joint has excited considerable discussion in this country in recent years, and in consequence there is much less tendency to discuss different causes and the different operations based on these causes. It may fairly be said that the nonoperative treatment, by braces, offers practically no relief, and that the operative treatment is confined almost entirely to methods of contracting the axillary portion of the capsule. The employment of a portion of the deltoid muscle as a flap passed under the humeral head as a sling support to prevent its escape from the socket has earned the right to be considered among the available methods of treatment. As much can hardly be said for dividing the muscles in the axillary folds to overcome their supposed effect in pulling the humeral head from its socket or glenoid cavity.

The advocate of any particular view as to the pathologic condition should offer not extensive argument but the results of treatment based on that point of view. Because of its reported results, operation to contract the axillary part of the capsule has become almost the only one performed at the present time. Without going into an extensive discussion of the subject, I would merely express the opinion that the passing of a flap of the deltoid muscle under the head and neck of the humerus, close to the axillary portion of the capsule of the shoulder joint, prevents further recurrences of the dislocation, or reduces their frequency, not by the support afforded the humeral head by the small portion of the deltoid, but by the cicatricial contraction of the axillary portion of the capsule. This results from the free exposure of it rendered necessary for passing the deltoid flap around it, and from the subsequent healing of the bared capsule in its wrinkled and folded condition which results from the Velpeau or adducted position in which it is bandaged.

I have developed at length the pathogenesis which I accept but can now refer to it in only a summary manner. I have referred to the all important abnormally relaxed axillary portion of the capsule as a hernial pouch which must be removed for a radical cure, and to this pathology I still adhere. But a few lines may be permitted for an attempt to account briefly for the hernial pouch. A dislocation is merely a fracture of the skeleton at a joint with displacement of the fragments, the fracture consisting in a tearing of the axillary portion of the capsule (Fig. 1 *B*). A similar but milder capsule tear without dislocation occurs in a sprain, or as great a tear when a dislocation and spontaneous reduction occurs. The cause is the extreme movement of abduction from a force beyond what the ligament will withstand. These joint ligaments are as strong as or stronger than the bones between the joints, as is shown by the fact that fractures of the surgical neck of the humerus are much more frequent than dislocations of the shoulder, at least if we disregard the unknown number of dislocations that become spontaneously reduced. The same thing is true at the elbow.

---

[*] Read before the Section on Surgery, General and Abdominal, at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

[*] Because of lack of space, this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints. A copy of the latter will be sent by the author on receipt of a stamped addressed envelop.

Dislocations there, while common, are not nearly as common as supracondylar fractures of the humerus.

Hyperabduction at the shoulder joint in the cadaver with sufficient force always results in a typical anterior or subcoracoid dislocation, never any other kind. Practically all dislocations of the shoulder joint in life are anterior or subcoracoid. Therefore, hyperabduction is the cause of this dislocation. If one objects to such simple reasoning, let us ask, Did any one ever offer better evidence for any other mechanism, or as good? The most generally accepted fracture mechanism is that of Colles' fracture. Did any one ever prove that Colles' fracture is due to the fall on the hand? If so, how? Does any one deny this mechanism today? The same questions may be applied to Pott's fracture or any other fracture or dislocation, so far as establishing its mechanism is concerned. I now wish merely to justify as well as I can, briefly, my assumption that the typical and common anterior dislocation is due to hyperabduction.

NATURE OF ANTERIOR DISLOCATIONS

Normal abduction is limited primarily by the axillary portion of the joint capsule. Hyperabduction tears it, and if the force is great enough, turns the head out of the socket into the axilla, the torn capsule margins being pushed apart to permit so much displacement (Fig. 1 *B*). After reduction, the margins of the tear become approximated, and with the arm at the side of the body the torn region of the capsule becomes shortened by folding on itself, so that if the arm remains in this position until the torn capsule margins become reunited by cicatricial tissue, the whole axillary portion of capsule in its folded condition becomes involved in the cicatricial tissue and consequently shortened, resulting in limited abduction and external rotation, and in the early stages pain on abduction (stiff and painful shoulder). But if the arm is carried forcibly into abduction before the cicatricial healing is strong enough to resist stretching of the scar, with or without slight tearing of this new cicatricial tissue, a new dislocation develops from a degree of force much less than necessary to produce the first dislocation. Repeated dislocations prevent the contraction of the capsule to or within the normal length, and this abnormally lengthened capsule permits easy recurrence without fresh tearing, so that on reduction, no reparative inflammation follows and consequently little or no pain or disturbance of motion.

If the capsule has been contracted by operation, a new dislocation can follow from sufficient force, but only with the production of a new tear of the axillary capsule with consequent reparative inflammation and new cicatricial tissue about the tear. If, after the reduction of the new dislocation, the arm is kept at the side for four or five weeks again, the cicatricial tissue produced by the operation will be added to or reinforced, and a new dislocation rendered almost impossible without a second operation. This is the point which I would most emphasize in this paper; i. e., that if a recurrence should follow operation, a second operation will not be necessary in a nonepileptic patient, because the new tear and the consequent new cicatricial tissue with the arm fixed in the Velpeau position for four or five weeks will make the axillary portion of the capsule much stronger than the repair from the operative scar tissue did. One need not be concerned about stiffness of the joint afterward. A slowly returning motion makes a stronger joint than a rapidly returning motion.

TREATMENT

No operation yet reported, except those affecting the bones, has shown itself proof against failures, but capsulorrhaphy has come nearer to such a result than any other. According to my interpretation, my results to date show that it offers close to 100 per cent. cure of the dislocations, and close to 100 per cent. functional results in nonepileptic patients. In only one case was a second operation done, and in only three were the dislocations not stopped. These were the only patients who could not be controlled and who consequently did not follow instructions after operation. In a nonepileptic patient, a dislocation following operation is *an advantage, not a disadvantage in that particular case.* An inguinal hernia recurring after operation cannot be cured without another operation. A shoulder dislocation recurring after a capsulorrhaphy can be cured probably more certainly, and surely more safely, without a second operation than with one. If the capsule repaired by the operation is not as strong as normal or as strong at least as is necessary for the needs of that particular patient, then the quicker another dislocation takes place, the better for that patient.

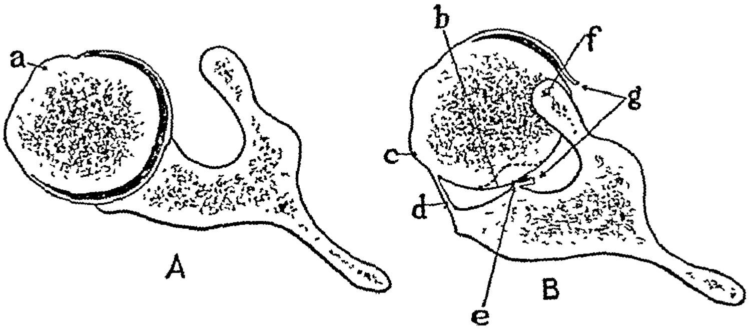

Fig. 1.—*A*, diagrammatic transverse section of skeleton of left shoulder joint at about its middle *B*, same parts in the position of an anterior or subcoracoid dislocation, showing the anterior portion of the capsule torn at the glenoid margin and the torn margins thrust aside by the dislocated humeral head The gap between these torn margins becomes filled in by new or cicatricial capsule, as the gap between the divided ends of a contracted Achilles tendon become bridged together by new or cicatricial tendon The capsule thus lengthened permits recurrent dislocations without fresh tearing of capsule and reparative inflammation afterward. The humeral head dislocating in abduction great pressure on the posterior surface of the head results when the arm falls to the side of the body This accounts for the groove in the head (shown by dotted line) which I have found in every case in which I have operated. It sometimes represents the loss of a fourth or a third of the head If when the arm falls to the side this pressure is not great enough to lock the head in dislocation, then a spontaneous reduction occurs In a recurring subluxation (snapping shoulder) only temporary locking in abduction takes place, and the head snaps back into the joint on certain movements of the arm In a high excision of the humeral head (position of saw cut indicated by line *b*) the head is sawed off just above the anatomic neck and a little outside the pressure groove, so that the only portion of the head that leaves the socket in a dislocation is removed and nothing is left to be dislocated: *b*, position of saw cut, *c*, greater tuberosity, *d*, taut posterior capsule; *e*, anterior glenoid margin; *f*, coracoid process, *g*, torn fragments of capsule.

After the necessary period of caution following operation, say three or four months, when cicatrization may be considered completed, I advise the most violent use of the arm that the patient is willing to make. Before the operation, there was a hernial pouch of capsule large enough to receive the dislocated humeral head so that no trauma or tearing of capsule occurred, and consequently, after reduction, no inflammatory reaction or formation of new cicatricial tissue. After operation, in a new dislocation, the head must tear its way out at its weakest place, so that after the reduction new cicatricial tissue must form just where it can best reinforce the capsule. If relaxation and shortening of this axillary portion of capsule is maintained five or six weeks by bandaging the arm in the Velpeau position, the most important part of the capsule will be shortened and thickened as effectively as, if not more effectively than, it could be by a second operation. In other words, the first dislocation following operation produced a pathologic condition similar to that resulting from the original dislocation. If that had been treated properly, the patient would probably never have developed a recurrent dislocation. Instead, he would have had a stiff and painful shoulder, which is the chief purpose of a capsulorrhaphy in these cases. The stiffer the shoulder when the bandages are removed, the better the prognosis. In any case, at this stage the patient can abduct the arm to a level with the shoulder, which is sufficient for most functioning of the limb. There is no occasion to worry about a permanent ankylosis. There is more occasion to be concerned about a rapid return of full motion. In any case, another dislocation properly treated will result in a stronger joint.

RESULTS

In only one of my cases was a second dislocation necessary to give a sufficiently strong joint to withstand the strains put on it by the patient's needs, and the strains put on the affected joint were more severe in this than in any other of my cases. Nearly three years after operation, in defending his title as college champion wrestler in the 158 pound class, he sustained a dislocation of the shoulder operated on. More than four years later, in a boxing contest, he dislocated it again. In the nearly eight and a half years since then, it has given him no further trouble, although he has kept up continually vigorous athletic work, boxing, swimming, and anything else he has an inclination to do.

What we need most now are reports on the late results in the patients operated on, and such reports are growing. Recently Valtancoli[1] reported the results in thirteen patients operated on, capsulorrhaphy being the only operation performed. The immediate results were good in all. The late results were learned in nine cases. Of these, in six the results were faultless, in one good, and in one (an epileptic patient) wholly negative after the first operation, but excellent after the second operation. In the remaining cases the result was good for seven years, but during military service the trouble recurred and has persisted. He summarized his results as follows: The operation was successful in 86 per cent. (with complete restoration of function), cure with reduced function in 7 per cent., and failure in 7 per cent.

I have operated on fifty-seven shoulders in fifty-three patients, eighteen shoulders in epileptic and thirty-nine in nonepileptic patients. Of the latter, three were of the "snapping shoulder" variety or recurrent subluxations. Since my last report,[2] no additional epileptic patients were operated on. Of these eighteen, a capsulorrhaphy was done first in seventeen. After three capsulorrhaphies with failure, a high excision of the humeral head was performed six years ago, and since then there have been no more dislocations in that shoulder. Shortly afterward, a recurrent dislocation developed in the other shoulder of this patient, the dislocation being repeated with every convulsion. The patient being very muscular, the convulsions were very violent and they were very frequent. Since he was of low mentality, permanently confined to an asylum and difficult to control, it was decided that a high excision was indicated without resorting to a preliminary capsulorrhaphy.

The results in the eighteen shoulders in epileptic patients are summarized as follows:

No recurrence after one capsulorrhaphy: Ten cases, or 55.5 per cent., the first patient being operated on fifteen and one half years ago, the last six years ago.

No recurrence after two capsulorrhaphies: Two cases, or 11 per cent; last operation in first case five years ago, and in second case, three years ago.

Capsulorrhaphy thus was 66.5 per cent. successful in epileptic cases and a failure in six shoulders, or 33.5 per cent.; but bone operations stopped the dislocations completely in five of these and were not tried in the other. These six may be tabulated as follows:

No recurrence after high excision of the humerus: Four shoulders, or 22 per cent. of the eighteen epileptics; this operation done in the first shoulder six years ago and in the fourth, three years ago.

No recurrence after reshaping glenoid cavity: One case, or 5.5 per cent.; operation, fifteen and one half years ago.

Recurrences after two capsulorrhaphies: One case, or 5.5 per cent.; last operation, thirteen and one half years ago.

It is my belief that a dislocation after a high excision of the humerus is impossible because the only portion of the humerus that can leave the socket in a dislocation is removed by this operation (Fig. 1 *B*), and that a dislocation will not occur after a reshaping of the glenoid cup. Hildebrand,[3] who seems to have originated this operation (reshaping the glenoid cavity), operated on two patients with normal motion developing later in both cases, and no recurrences at the time of reporting them. I know of no other reported cases. I described and illustrated each step of the high excision of the humerus[4] and the functional result[2] in a case in which this operation was done in both shoulders for recurrent dislocation, as well as the roentgen-ray findings long after the second operation. The functional result is between 70 and 80 per cent. of the normal in both shoulders, although the patient is mentally defective from his epilepsy, and little disposed to take the exercises necessary for the development of full function. In an epileptic patient who has the mentality to work for and appreciate full function, in whom the capsule operation has positively failed, I would give the preference to the Hildebrand operation, although it is not as easily done, because it appears to offer the best chance of normal function from suitable exercises.

Of the thirty-nine nonepileptic cases, a single capsulorrhaphy was done in all, with the exception of one early case in which two capsulorrhaphies were done. With the proper care, this operation is sufficient, in my opinion, to stop the dislocations entirely and to give a normal functional result. Three have not been heard from recently, and three others were of the "snapping shoulder" or recurrent subluxation variety. The remaining thirty-three cases may be thus summarized:

No dislocation since operation in twenty-two cases, or 66⅔ per cent.; first patient operated on seventeen and one-half years ago, and last six months ago.

One dislocation since operation in seven cases; in the first case, this dislocation occurred in the first year after operation, which was fifteen and one half years ago, and in the last case this dislocation occurred three years after the operation and only two months ago.

[3] Hildebrand: Arch. f. klin. Chir. **66**: 360, 1902.

[4] Thomas, T. T.: Ann Surg. **66**: 492 (Oct.) 1917.

Two dislocations since operation in one case; first dislocation, three years after operation, and second dislocation, seven years after operation, or eight years ago.

Acknowledged failures, two cases; refused or ignored direction after operation; probably hopeless without further operation.

One case still very hopeful without further operation, if he submits to direction which he has as yet ignored.

Every writer on this subject in the past, according to my knowledge, has regarded a dislocation following operation as establishing the failure of that operation. In my opinion, a proper understanding of the pathology of the original dislocation, of the recurrent dislocations and of the first dislocation following operation, shows us how to obtain, after this first postoperative dislocation, by the proper use of the pathologic changes, a positive and permanent cure without further operation; i. e., how to make the joint as strong as normal or stronger, if this is desirable. Of these thirty-three cases, we find that the operation itself was sufficient for a cure in twenty-two cases or 66⅔ per cent. In seven others, one dislocation after operation was necessary to supplement the operation, and in another, two dislocations. A successful result was thus obtained by the operation, directly or indirectly, in thirty of the thirty-three cases, or 91 per cent. The character of the work done by these eight patients since the last dislocation is convincing and makes these cases most interesting and important, because they solve the most important problem in the whole subject. They are briefly summarized as follows:

Case 1.—An athlete, now a physician, was operated on more than fifteen and a half years ago, and within the first year, owing to violent wrenchings, had the sensations of momentary dislocations or subluxations, but has never had any further trouble, although he has continued his athletic exercises, and was thrown from a horse.

Case 2.—A heavy weight student wrestler was operated on about a month after Patient 1, and afterward became the champion wrestler of his college; but in a wrestling bout three years after the operation he redislocated the same shoulder. He later went back to heavy gymnasium work and permitted himself to be photographed standing on his hands, because he was taking much greater risks in the gymnasium every day. Seven years after operation, he again dislocated this shoulder in a boxing match, but in the eight years since he has done "all kinds of athletic work" without any further trouble in the shoulder.

Case 3.—A strong man, operated on more than eleven and a half years ago, redislocated the same shoulder when a horse fell on him seven months after the operation, but has never had any further trouble, although he has done "all kinds of hard work."

Case 4.—A gymnasium instructor was operated on six years and nine months ago, and eight months later had a redislocation in a basketball game, but has had none since. He wrote recently that the shoulder operated on (left) felt just as strong as the right, and he used the two about equally, and that the motion was perfect. In publishing a report of this case in 1921 (compared to the preceding three cases, it was comparatively recent then), I said that I believed that this patient had as good prospects as the others had had in the corresponding stage. This is now confirmed.

Case 5.—A college student was operated on, June 12, 1915, and he redislocated the same shoulder, Oct. 21, 1922, more than seven years later, while he was attempting to mount a horse without a saddle. As he jumped up to straddle the horse, it moved; his arms were stretched out in his effort to hold on to the horse when the dislocation occurred. This happened on a ranch in South Dakota, and the patient lived in Iowa, so he waited until he reached home five days later to have the arm bandaged in the Velpeau position, but held the arm close to his side during that time. Since then he has played tennis and golf with no ill effects, and can throw a ball. In tennis, he plays and serves without reservation. He still lacks confidence in the shoulder and wishes to know how to gain it. The answer is to take another dislocation if it can happen, and immobilize the arm properly afterward.

Case 6.—An ex-service man and coal miner was operated on, June 2, 1920, and had a redislocation, April 24, 1921, but has had none since. March 23, 1925, he wrote that the affected arm could not be in better condition, that he has continued to work hard as a coal miner, and that he is a baseball player, throwing the ball with the hand of the affected side.

Case 7.—A dental student was operated on, June 13, 1922, and had a redislocation, March 14, 1925. While watching a basketball game he suddenly realized that the ball was coming toward him, and he put up the right hand to stop it. The right shoulder had been operated on. The ball drove the arm into extreme abduction and external rotation, the most dangerous position for the occurrence of dislocation, which resulted. It was reduced immediately and the arm bandaged in the Velpeau position, but his physician released the arm from the bandage in nine days. Twenty-six hours afterward while lying on his back, he allowed the arm to fall into abduction and external rotation, and another dislocation occurred. After reduction and bandaging in the Velpeau position, he came to Philadelphia, a distance of about 200 miles. The arm was kept in this position for eight weeks, when the shoulder motion was considerably limited, this being the desired result. The prognosis given in 1921 for Case 4 can be given for this case now with equal confidence.

Case 8.—A college student, aged 19, was operated on, June 17, 1921. Before operation, he would have as many as three dislocations in one basketball game. After operation, he continued to play basketball as before, and to do anything he wished to without fear. Nov. 10, 1924, he redislocated the same shoulder while wrestling, reduced the dislocation himself, but did not bandage the arm at the side at any time afterward. He has not engaged in athletics since then, but does his usual work without fear, lifting boxes and other weights above his head with the affected arm in full abduction and external rotation, the most dangerous position for the occurrence of a dislocation. In this position, he has some tightness in the axilla and a slight restriction of abduction, which adds to the ability of that joint to resist dislocation. I advised him to force the movements of the shoulder to the limit, and to welcome another dislocation if he can produce it. The chances are that he will not, but he has promised to permit me to direct his course afterward if another dislocation occurs.

The following two cases are failures and the third is likely to be:

Case 9.—A young man was operated on, Jan. 5, 1913. Jan. 17, 1914, he redislocated the same shoulder with slight violence and again, Oct. 14, 1914. On neither occasion did he return to me for direction. At this time, I had not discovered the curative advantages of a postoperative dislocation, so that when the patient's physician sought relief for him, I urged a second operation, which was equally unsuccessful. This is the only nonepileptic case in which I performed a second operation, and probably it will be the last.

Case 10.—A strong young man, operated on, May 25, 1918, was never seen by me after he left the hospital, about two months after the operation. Aug. 5, 1919, while repairing an automobile, in reaching for a difficult position, he wrenched and dislocated the same shoulder. He did not immobilize the arm afterward and soon had another dislocation, and after this more of them.

Case 11.—A college teacher was operated on, Feb. 1, 1921, and after leaving the hospital at the end of a week, was not afterward seen by me. He redislocated the same shoulder, Sept. 11, 1922, while going through some setting up exercises. Jan. 4, 1925, the same dislocation recurred from sneezing while the hand was outstretched on a banister. An effort was made recently to see him, but without success. It is likely that the condition will become as bad as before the operation.

POSTERIOR DISLOCATIONS

Of the fifty-seven shoulders operated on, there were three with posterior dislocations in two patients, both men and epileptic. In three other men both shoulders were involved, but the dislocations were all anterior. Two were epileptic and one not epileptic. As the brief statistics show, anterior dislocations of the shoulder are very much more common than posterior, and it is a little interesting to note that in one case a posterior dislocation occurred on both sides. On the theory of chances, one of them should have been anterior; but while I have not seen or read of another bilateral posterior recurrent dislocation, I am inclined to believe that the occurrence of the same dislocation on the two sides is not an accident. I have many times produced an anterior dislocation of the shoulder on the cadaver by hyperabduction, never a posterior. Occasionally a typical fracture of the greater tuberosity of the humerus would be associated with the anterior dislocation thus produced. So far as I can recall, when I found a fracture of the tuberosity associated with the dislocation I always made a similar dislocation in the opposite shoulder and always obtained a similar fracture of the greater tuberosity with it. I could not avoid the impression that there was something in the anatomy or construction of the skeleton in that person or cadaver to favor the occurrence of this fracture with the dislocation. There is no attempt here to explain but to state an interesting fact.

According to Valtancoli,[5] Krönlein found one posterior among 207 shoulder dislocations, Finckl, five among 206, and Valtancoli, five among 140. Schlaepfer,[6] among 120 shoulder dislocations, found 113 (94 per cent.) anterior and seven (6 per cent.) posterior. When the findings of all four are added, we find eighteen posterior among 673 shoulder dislocations, or 2.7 per cent. My three posterior dislocations represent about 5 per cent. of the total fifty-seven shoulder recurrent dislocations.

The capsule is always lax where the humeral head leaves the socket, in the axilla in the anterior dislocation and under the spine of the scapula and acromion in the posterior, and a capsulorrhaphy must be done at the site of the laxity in order to contract it. The posterior operation was done in all three shoulders, which were in epileptic patients, and in none has there been a dislocation since operation. The function is perfect in two and nearly perfect in the other. The operation will be described and illustrated in connection with all the operations employed.

SNAPPING SHOULDER

Snapping shoulder, though rarely mentioned in textbooks on surgery, is a real and disabling condition. While I have observed and operated on three patients, with fair success in the first, and marked success in the second and third, and while I have a conviction, I would hardly feel justified in expressing a positive opinion regarding its basic cause. Kappis[7] adds two cases by Parona and Riedinger to the eleven already reported, and sums up as follows:

> The joint as a whole, by voluntary activity, is brought into an abnormal position so that it jerks away from a tense muscle with a snap, generally backward. In disease or paralysis, such a process may take place habitually and involuntarily. Habitual luxations can also sometimes be brought about voluntarily, and more rarely restored to position voluntarily, causing a kind of snapping. A sort of shoulder snapping is accounted for by the fact that the normal joint movements are inhibited by some intra-articular cause, and the inhibition is overcome by a sudden snapping.

While this does not explain the condition, it does emphasize its intra-articular character. Bristow[8] operated on a woman, aged 31, in whom the condition resulted from two falls at the age of 16, and found that:

> From the outer side of the short head of the biceps, muscular fibers were taking origin, running downward and outward to the long head. On abducting and rotating the arm, this fleshy muscle rode over the lesser tuberosity. About 1 inch [2.5 cm.] of this—that part coming in contact with the lesser tuberosity—was removed with a strip of the tendon of the short head of the biceps to which it was attached.

Recovery was uneventful, and the patient could afterward play tennis, which she had not been able to do before. The cause assigned here is entirely extra-articular, and since I believe the cause intra-articular, I would offer the following criticism: The riding of the short head of the biceps over the lesser tuberosity is a normal movement and is abnormal here only to the degree that the movement of the whole humeral head is abnormal, because of an abnormal joint condition.

Kappis observed that the humeral head generally snapped backward. In Case 14, there was a difference of opinion on this point. In Case 15, it was noted that the snap was upward and forward, which was the final conclusion in Case 14; but in Case 16, it was concluded that the snap was backward. In all three cases, there was the conviction that we were dealing with an intra-articular condition in the nature of an abnormal range of or a subluxating movement of the humeral head. In Case 14, two surgeons were responsible for the site of the capsulorrhaphy, but in Cases 15 and 16, I alone was responsible. I decided in favor of anterior or axillary capsulorrhaphy, because about 95 per cent. of my other and complete dislocations were anterior, and these were probably of the same type. Because of the uncertainty during the operation in Case 15, a posterior capsulorrhaphy was added with the hope that whichever was present it would be controlled. The end-result was perfect. In Case 16, although the snap seemed to occur backward, the anterior operation alone was performed, and a perfect end-result was obtained. Therefore, in future cases, I expect to do the anterior operation until the results do not justify it.

RECOVERY OF MOTION AFTER CAPSULORRHAPHY

The recovery of motion after a capsulorrhaphy needs very little discussion. I am never concerned in a nonepileptic patient or in an epileptic patient of good mentality. Only epileptic patients of impaired mentality preserve restricted movement, because they will not tolerate any pain and they do not appreciate the necessity for the necessary exercises. Indeed, when the relatives or friends of such patients or the attendants who care for them in institutions are asked about the result of the operation, they are usually enthusiastic, and do not seem to know that some patients cannot elevate the arm normally. Their attention has not been called to it because the patients do not complain, and because the occasion for full abduction rarely arises in their presence. Epileptic patients of good mentality, and especially those who must earn their livings, recover motion about as well as nonepileptic patients.

[8] Bristow, W. R.: J. Bone & Joint Surg. **6**: 53 (Jan.) 1924.

Examples of this are seen in the preceding case reports of posterior recurrent dislocations.

There is, however, real need for concern about too early return of motion after a capsulorrhaphy, so that I advise the patient to preserve some stiffness at least for five or six months, and am pleased if, at the end of a year, there is some tightness in the axilla on full abduction. There is some reason to believe that if, after a capsulorrhaphy in an epileptic patient the arm is held in the Velpeau position, preferably in a plaster cast, for three or four months, a recurrence would not follow and consequently a bone operation would not be necessary; but a high excision of the humeral head will positively stop all dislocations, and a Hildebrand reshaping of the glenoid cavity will probably do so. After the former, nearly full function can be recovered, and after the latter, probably full function. These operations will probably never be indicated except in epileptic patients, and in them only very rarely.

I have previously discussed the operations I have done for this condition except that for the posterior variety, and that will be described and illustrated here. In my first twelve shoulders, the axillary operation was done between the coracobrachialis muscle in front and the axillary vessels behind.[9] These were all anterior dislocations, and in all of this kind since, except a high excision in one shoulder of an epileptic patient and a deltopectoral capsulorrhaphy in one snapping shoulder, the capsulorrhaphy has been done just posterior to the axillary vessels[10] The Hildebrand operation for reshaping the glenoid cavity[2] was done by the posterior route as described below and consists in chiseling away the posterior margin of the glenoid cavity, while the humeral head is in the anterior dislocated position and the cavity empty, until the anterior margin is abnormally raised above the posterior margin and offers an apparently insuperable obstruction to an anterior dislocation. The result in my case is exceptionally brilliant.[11] There has been no recurrence in the fifteen and a half years since, although the convulsions have continued to be violent and frequent.

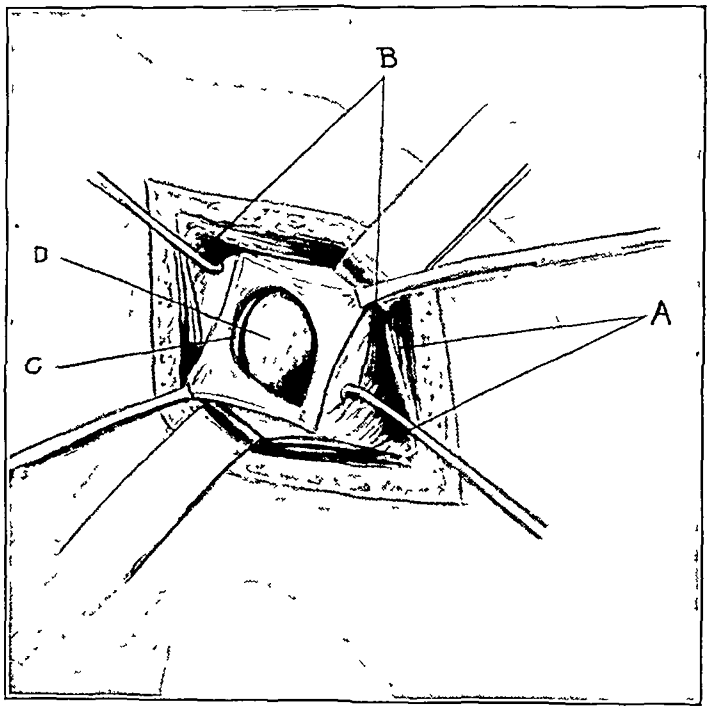

Fig 2—Exposure of shoulder joint posteriorly for overlapping of capsule for posterior dislocation or chiseling away the posterior margin of the glenoid cavity (Hildebrand) for a rebellious anterior dislocation, the head being dislocated forward out of the way during the operation: *A*, separated margins of the deltoid; *B*, separated margins of divided infraspinatus; *C*, posterior margin of glenoid cavity, *D*, posterior surface of humeral head and about the location of the groove usually found in the head in recurrent dislocations The divided capsule margins held by tissue forceps are easily overlapped by mattress sutures

TECHNIC OF POSTERIOR CAPSULORRHAPHY

The posterior capsulorrhaphy (Fig. 2) is done as follows: An incision about 6 inches (15 cm.) long is made from the spine of the scapula downward in the line of the fibers of the deltoid muscle, a little below the head of the humerus, or about midway between it and the lower or posterior margin of the deltoid. When made along the posterior margin of this muscle, too strenuous retraction forward of the deltoid flap is necessary for exposure of the capsule. The incision is deepened through the posterior fibers of the deltoid, and the underlying rotator muscles, infraspinatus and teres minor are exposed, and their fibers found running at about right rangles with those of the deltoid. The capsule lies under the infraspinatus and teres minor, and may be exposed between these two muscles, or perhaps more easily by splitting the fibers of the infraspinatus, making a muscle splitting incision not unlike the McBurney for appendicitis. One should not forget that the circumflex nerve is passing backward in the lower end of the wound to enter the deltoid about the center of its under surface, and from that point to radiate in all directions. After dividing the infraspinatus in the line of its fibers, and retracting the margins of this muscle as one retracts the margins of the internal oblique and transversalis in the McBurney incision, the capsule is exposed. It is divided about midway between its humeral and glenoid attachments, and parallel with both (Fig. 2), and the margins are overlapped with mattress catgut sutures, the arm being held in external rotation to relax this portion of the capsule. A continuous catgut suture for the infraspinatus wound, another for the deltoid, and silkworm-gut sutures for the skin close the wound without drainage. A gauze dressing and bandage are applied and the arm fixed at the side in full external rotation, preferably by a plaster cast. The Velpeau position gives perfect relaxation of the capsule for *the anterior* dislocation and axillary operation, but the opposite position is necessary to give as good relaxation for the posterior operation; i. e., full abduction and external rotation. But this is rather a difficult and uncomfortable position to maintain. As shown in the cases reported, I have tried this position, also full external rotation and half of full abduction (the arm on a level with the shoulder and the forearm upright), and in one case, the arm at the side of the body and in full external rotation (the forearm in line with the transverse axis of the body). The last was the most comfortable position, and as it gave as good end-results as the others, I expect to use it in the future.

[10] Thomas, T. T: Surg, Gynec & Obst (Jan) 1914 (description); ibid **32**: 291 (April) 1921 (illustrations)

[11] Thomas, T. T.: Surg, Gynec. & Obst. **32**: 291 (April) 1921 (Case 6).

CONCLUSIONS

1. A recurrent dislocation of the shoulder joint is the equivalent of an ununited fracture, in that abnormal motion is permitted at the site of both breaks in the skeleton. The treatment in both is to remove the abnormal motion.

2. The best method of accomplishing this purpose in the anterior recurrent dislocation is by an axillary capsulorrhaphy, which is one of the simplest, safest and most effective major operations in surgery, and very rarely requires hospitalization for more than one week.

3. Return of motion after a capsulorrhaphy, from ordinary use of the arm, is sometimes too rapid to permit complete cicatrization before the joint is exposed to full violence. Therefore, operative stiffness is to be preserved rather than feared. Three fourths of full motion at the end of three or four months is satisfactory, and some tightness in the axilla on full abduction of the arm at the end of a year is a good sign. Normal motion after a capsulorrhaphy always develops in a nonepileptic patient or in an epileptic patient with mentality enough to desire it.

4. A dislocation following operation in a nonepileptic patient is an advantage in that particular case. It proves that the operative cicatrization was not sufficient for the needs of that patient and must be reinforced by the new cicatricial tissue following the new dislocation. In only one case was a second dislocation necessary to complete the cure. In thirty-three nonepileptic shoulders, a single capsulorrhaphy was successful in twenty-two without a further recurrence; in seven cases after one recurrence, and in one after two recurrences. This operation was a failure in three cases because the patients failed to take advantage of the curative effects of the first dislocation following operation.

5. A single capsulorrhaphy stopped the dislocations permanently in ten of the eighteen shoulders in epileptic patients. In two more, two capsulorrhaphies were necessary. In four, a high excision of the humeral head and in one a reshaping of the glenoid cup were necessary to prevent the dislocations. In the remaining case two capsulorrhaphies failed and no bone operation was performed.

6. A snapping shoulder is a recurrent subluxation of the shoulder joint, probably of the anterior variety, as with the recurrent complete dislocations. An axillary or anterior capsulorrhaphy will probably cure in every anterior subluxation, and may cause sufficient general contraction of the capsule to prevent the snapping of a posterior subluxation. If it does not cure in any case, an added posterior capsulorrhaphy will probably complete the cure. This is important, because it may be impossible to determine which variety one is dealing with. In my opinion this is a more disabling condition than a recurrent complete dislocation, because the displacement and snapping back occurs many times a day, while the complete variety almost always occurs at much longer intervals, usually of weeks or months.

2009 Spruce Street.

ABSTRACT OF DISCUSSION

DR DAMON B PFEIFFER, Philadelphia: The treatment of recurrent dislocation of the shoulder still requires further efforts at standardization There is as yet no general agreement on the rôle of the bone, the muscles and the capsule in the production of this disability. It may be said, however, that the bony changes in the head of the humerus and the glenoid cavity are generally secondary to the initial or subsequent traumatism and only occasionally a factor in predisposing to succeeding dislocation. It has been shown that the muscles of the shoulder girdle have a pronounced effect in producing redislocation, and numerous proposals have been made to alter the muscle balance in such a way as to obviate the dislocating force of the great adductors of the arm which in the hyperextended position exert a pull on the head toward the direction of dislocation. Utilization of these principles has had considerable success, notably in the Clairmont and the Sever operations. It is a fair criticism of all operations based on tenotomy or transplantation of muscle that they are mutilating to a certain degree and are at times followed by weakness or partial disability, which may, indeed, be of little moment compared with the dangers and disadvantages of recurrent dislocation, but are, nevertheless, not desirable. Dr. Thomas deserves great credit for his insistence on the laxity of the capsule as the common cause of recurrent dislocation, and for the development of a simple technic for exposure and removal of the redundant portion. The sagging and laxity of the antero-inferior portion of the capsule is the chief, if not the only, reason for the recurrence of dislocation. The operation of excision of the slack portion of the capsule, with or without plication, provided only that healing in the new position is allowed to become firm before new strain is placed on it, is simple and leaves no disability, as a legacy of the operative procedure itself. It is the operation of choice. It will cure the vast majority of cases. When there has been capsulo-articular separation or extensive drainage to the margin of the glenoid itself it may not suffice, but those cases must be relatively uncommon and are to be determined only by operation and best by trial of the simpler procedure.

THE HEALING OF ARTERIES AFTER DIFFERENT METHODS OF LIGATION

AN EXPERIMENTAL STUDY *

J. S. HORSLEY, JR, M.D.
RICHMOND, VA.

Ligation of arteries has received a great deal of study since the time of Ambroise Paré. The healing of arteries after ligation in continuity was admirably described in 1886 by Warren.[1] In 1922, Leriche[2] of Lyons gave a very complete report of the remote results of ligations and resections of arteries from the functional point of view. The work of both these authors has been largely substantiated and confirmed in this study, which, however, is primarily concerned with a search for the best method of ligating a large artery so as to produce a permanent occlusion of the arterial channel.

The problem suggested itself to me a few years ago on hearing a verbal report of a patient with an aneurysm of the innominate artery who bled to death at a second operation after the innominate artery had previously been ligated. An attempt to open the aneurysm led to a terrific hemorrhage, which could not be controlled. Necropsy showed that the ligature had cut through and the arterial channel had been reestablished.

[2] Leriche, M. R.: Resultats éloignés des ligatures et des résections arterieles, Association française de Chirurgie XXXI Congrès français de chirurgie, Paris, 1922

A good many cases are reported in the literature in which, subsequent to ligation in continuity of one of the large arteries, the arterial lumen has been reestablished No cases have been found in which this has occurred after multiple ligations with division of the artery.

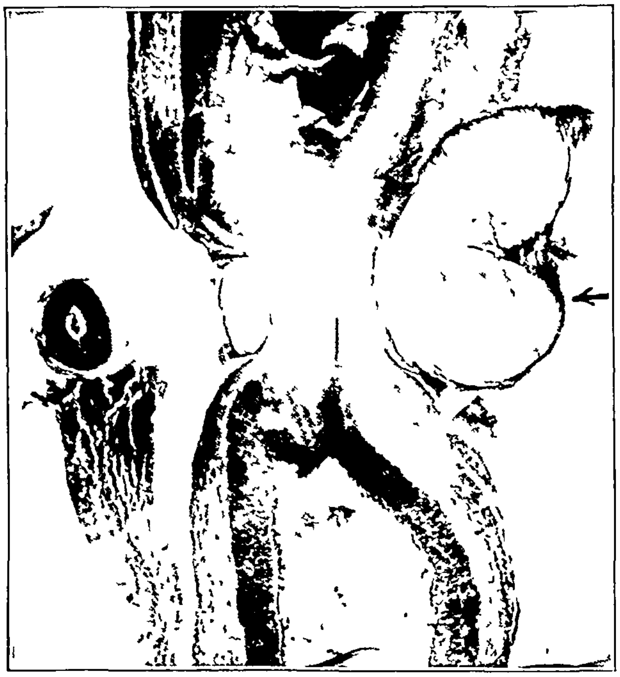

Fig 1—Longitudinal section of single ligature on femoral artery, 00 plain catgut, seven days after operation, magnification about 26 diameters

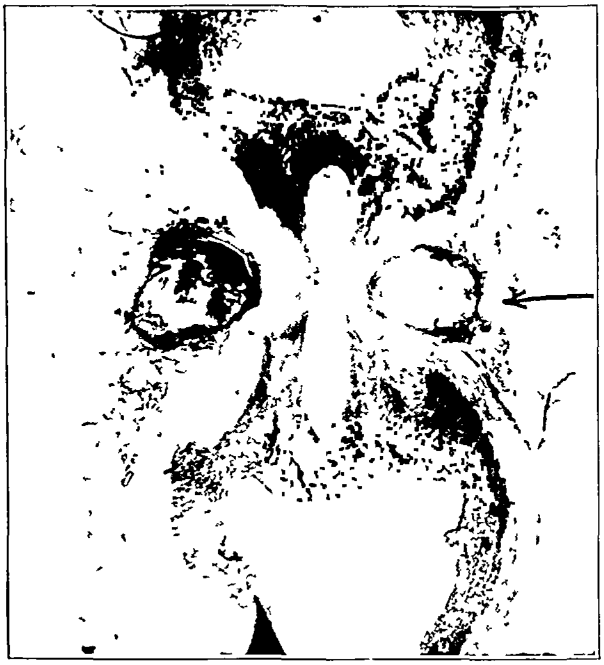

Fig 2—Longitudinal section of single ligature on femoral artery, medium linen, sixty two days after operation, magnification about 30 diameters

In 1907, J Shelton Horsley[3] ligated in continuity the right external iliac artery of a patient who had a fistulous opening between the external iliac artery and vein, which communicated externally and was the source of occasional terrific hemorrhages. This condition followed a wound from a rifle bullet Three weeks after the operation, the right common and external iliac arteries were ligated in continuity on account of recur-

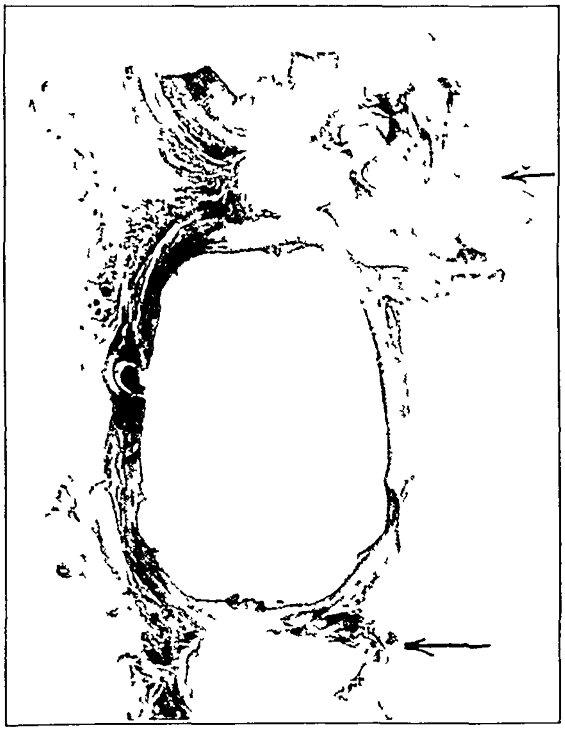

Fig 3—Longitudinal section of double ligatures on carotid artery, 00 plain catgut, fifteen days after operation, magnification about 17 diameters

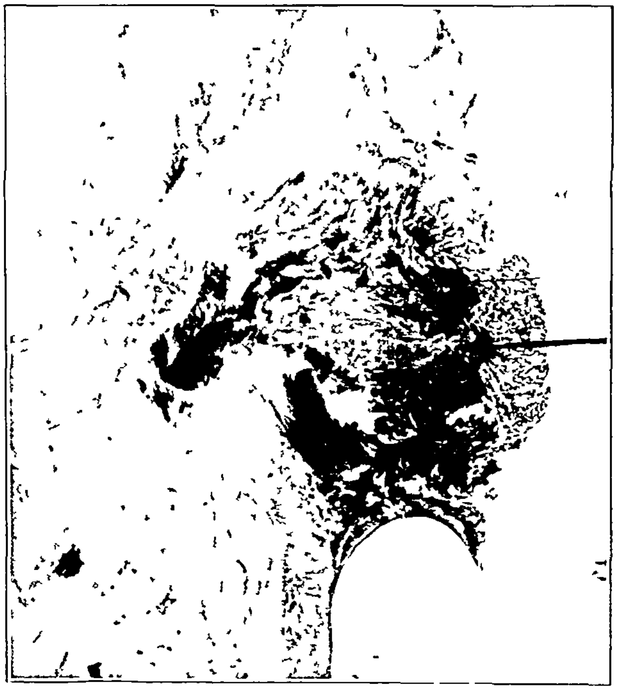

Fig 4—Longitudinal section of double ligatures on femoral artery, 00 plain catgut, forty days after operation Constriction of the walls of *the artery no longer exists, there is a tendency to canaliculization of the* occluding thrombus, magnification about 25 diameters

rent bleeding. Four weeks later there was another large hemorrhage, and the right common and external iliac arteries were again ligated in continuity, this time with silk instead of catgut. In four days the patient died of a sudden hemorrhage. Necropsy showed that the lumen of each vessel where the ligatures had been placed was partially reestablished.

---

[3] Horsley, J S Personal communication to the author

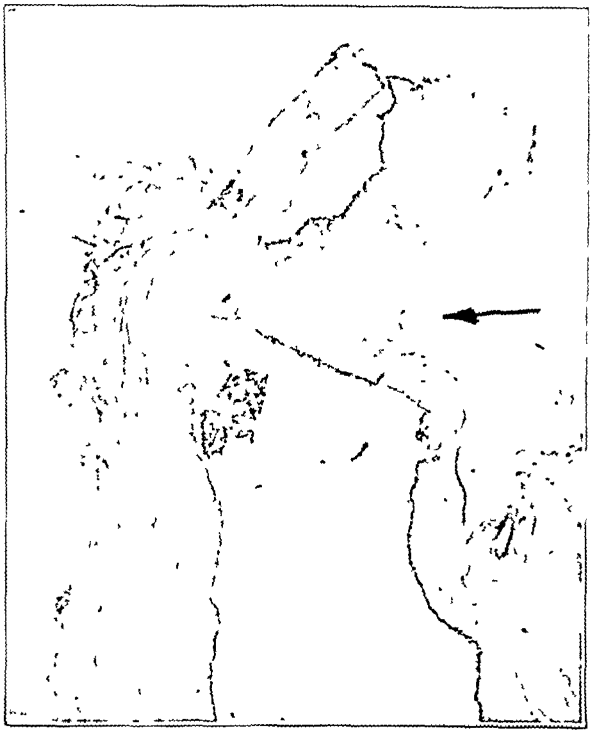

Fig 5 —Longitudinal section of single ligature on femoral artery, 00 plain catgut, thirty five days after operation A narrow band of tissue separates the lumens of the wide proximal portion and the contracted distal portion, magnification about 14 diameters

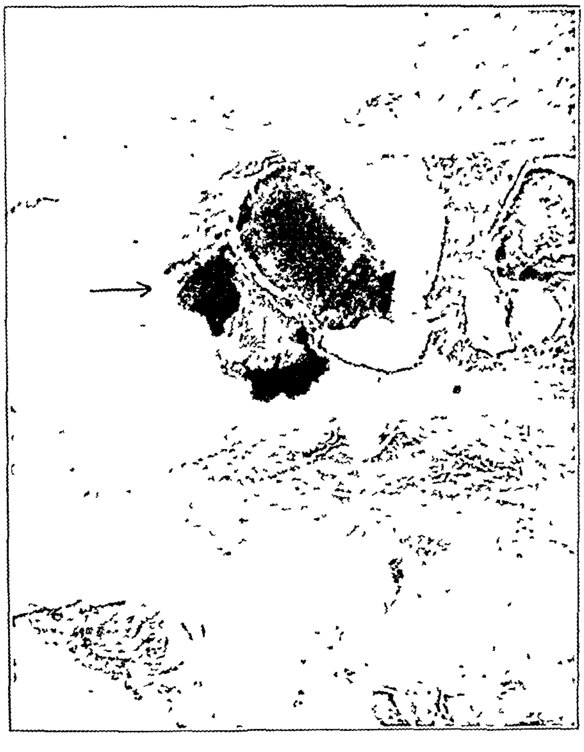

Fig 6 —Longitudinal section of double ligatures on femoral artery, 00 plain catgut, forty days after operation The arterial walls are no longer constricted by the ligature, and the lumen contains fresh blood clots with only a very narrow band of fibrous tissue occluding it, magnification about 25 diameters

In 1914, Thompson [4] of Galveston reported a case of ligation of the innominate artery, two ligatures of "bobbin" (the narrow linen tape used for tying the umbilical cord in obstetrics) being tightly tied side by side. Sixty-seven days after operation the patient died, and at necropsy the arterial lumen at the site of the ligatures easily admitted the end of a fair sized probe.

In 1918, Hamann [5] of Cleveland reported a case of ligation of the abdominal aorta in which apparently complete occlusion by a firmly tied silk ligature was obtained. In three days a reappearance of the femoral pulse was noted. Death occurred six months later from hemorrhage from a bedsore, and necropsy showed the aorta to be only partially occluded

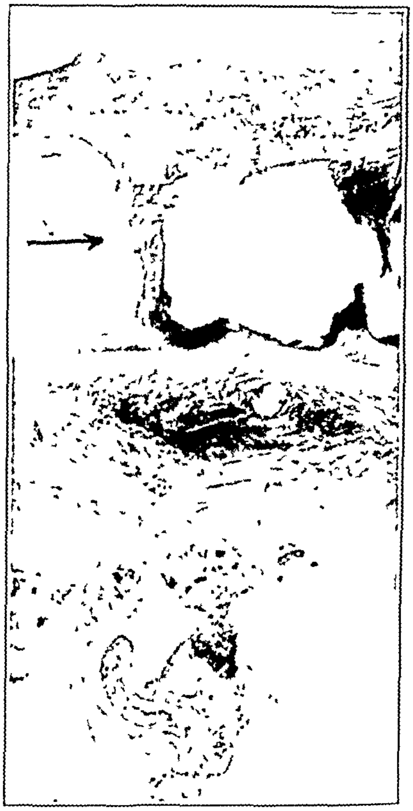

Fig 7 —Longitudinal section of same vessel as shown in Figure 6: This shows more distinctly the very narrow transverse band of tissue; the slight break in the fibrous band probably occurred during preparation of the section, magnification about 17 diameters.

Matas [6] reported a similar case in which double ligation of the abdominal aorta, with one-half inch woven cotton tapes, was performed for aneurysm at the bifurcation of the aorta. The patient died one year, five months and nine days after ligation. Necropsy showed that the original total occlusion had gradually been transformed into a narrow stricture. These five cases are cited to show the practical and clinical significance of this problem. Other such cases have been reported, and probably many more have been either unrecognized or not reported.

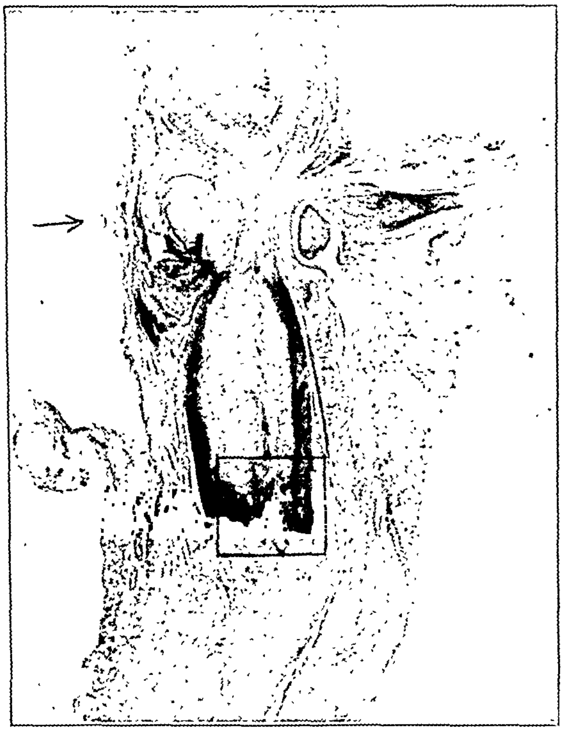
EXPERIMENTS

Single and multiple ligations of arteries of dogs with and without section of the artery were made. The ligatures used were plain and tanned catgut, silk and linen. Some of the operations were done under ether and some under local anesthesia. All experiments were preceded by the administration of large doses of morphin, and every effort was made to prevent pain or suffering. The brachial, femoral and carotid arteries were used. In all, eighty ligated arteries were studied. Some of the incisions healed by primary union, but most had a mild superficial infection with slightly delayed healing. Secondary hemorrhage did not occur in any of the dogs.

LIGATURES

The end-results following ligation with plain and tanned catgut, silk and linen were about the same. The catgut absorbed more quickly and the silk and linen ligatures tended either to cut through into the arterial lumen or to loosen. About the nonabsorbable ligatures occasionally a small amount of thick purulent-like material collected, but more often the ligature was completely encapsulated in the surrounding fibrous tissue. Reid [7] of Cincinnati has shown that catgut should not be used for the ligation of large arteries, since it may give way before the necrosed vessel wall becomes completely healed by fibrous tissue. This observation was confirmed in these experiments.



[illegible] section of distal ligature of femoral artery after plain catgut and section, fifty-eight days after [illegible] about 17 diameters.

LIGATIONS IN CONTINUITY

When a ligature is firmly tied, the intima and a portion of the media is ruptured, and the adventitia is compressed into a sheath around the constricted ends (Fig. 1). The earliest noted change is the formation of thrombi. The sizes of the thrombi vary greatly. They are larger when the vessel wall has been crushed or injured, and when sepsis occurs; otherwise the thrombi are small.

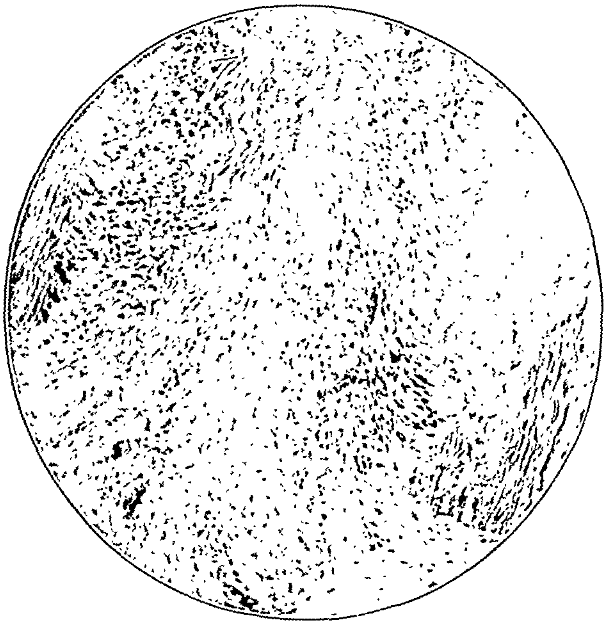


Fig. 9.—Higher magnification of [illegible] healed distal arterial end of same slide as Fig[illegible] plug. This field is outlined on the low power [illegible] reduced from a photomicrograph with a magnific[illegible]

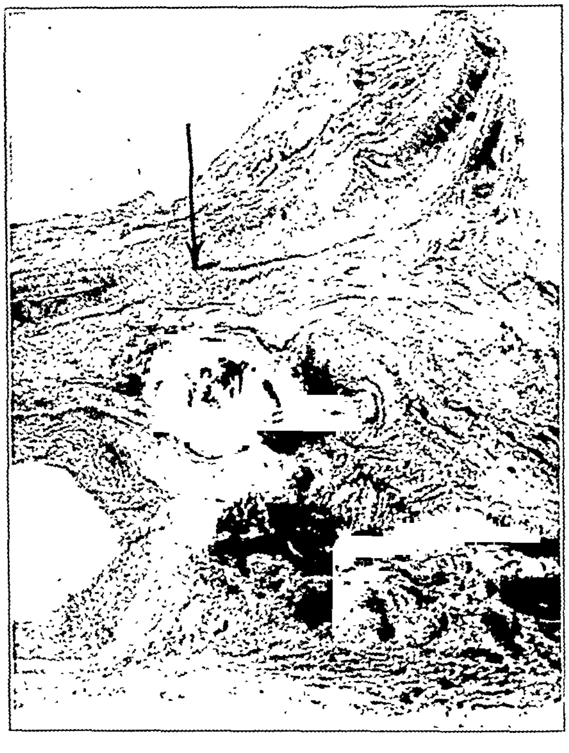

Fig. 10.—Longitudinal section of proximal ligature of femoral artery after double ligation with medium linen and section, sixty-one days after operation; magnification about 22 diameters.

During the first two to three days, an exudate and the swollen surrounding tissue bury the site of the ligature and form a callus for some distance above and below, depending on the amount of trauma and infection. This

callus tends to protect the vessel from secondary hemorrhage. Soon the ligatured area is invaded by leukocytes, and the ligature either loosens or cuts through the adventitia (Figs. 2 and 3). If it cuts through, the two ends of the vessel separate. Once freed the arterial ends begin to expand, and granulation tissue grows into the thrombi, producing an internal callus. With the granulation tissue new blood vessels are formed, which also penetrate the thrombi and may by canaliculization partially restore the occluded portion (Fig. 4). This stage usually occurs about a month after ligation. The vessel ends retract as the excessive repair tissue is absorbed, and a narrow permanent cicatrix is formed which usually closes the ends of the vessel. The cicatrix consists of three layers. The inner layer is composed of endothelium formed by growth from the intima; next to this is a layer of muscular tissue developed from the media, and externally there is a connective tissue layer.

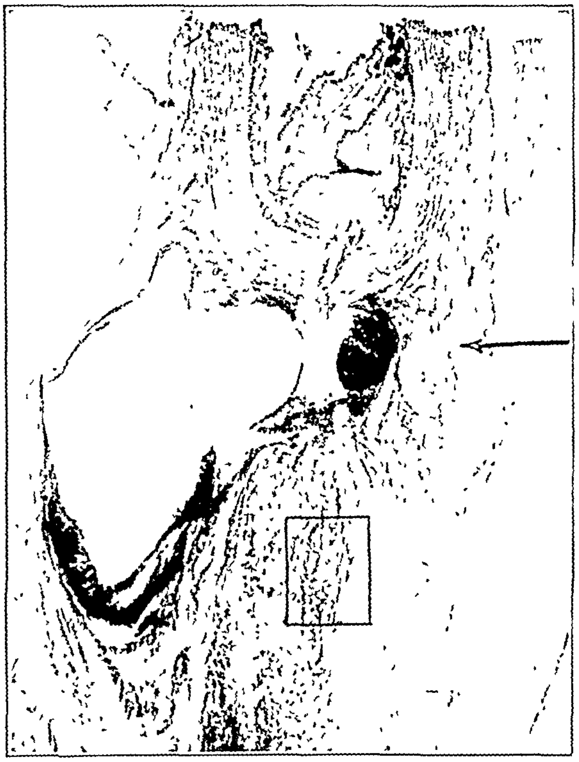

Fig 11.—Longitudinal section of proximal ligature of carotid artery after double ligation with medium linen and section, sixty four days after operation; magnification about 36 diameters

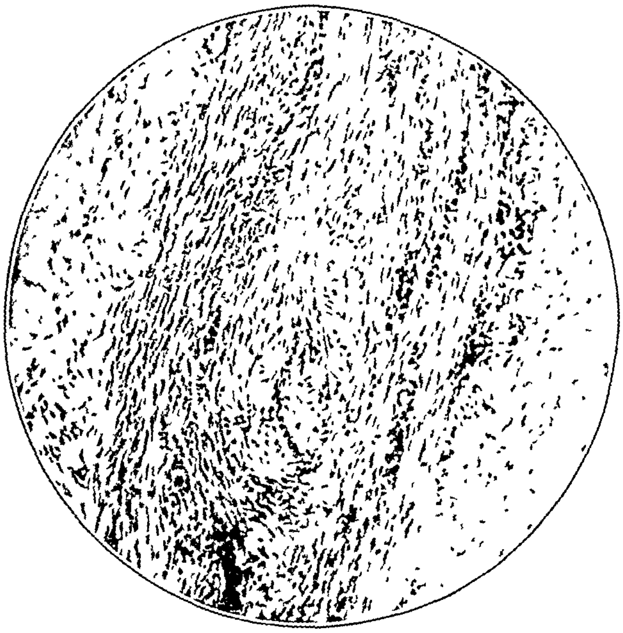

Fig 12.—Higher mag[illegible] n of healed proximal end of same slide [illegible] lug. This field is outlined on the low p[illegible] reduced from a photomicrograph with a [illegible]

Reestablishment of the arterial channel may occur during any part of this healing process by absorption, relaxation, or "cutting through" of the ligature into the arterial lumen, accompanied by either a dislodgment or canaliculization of the thrombus (Figs. 5, 6 and 7). The larger the artery and the higher the arterial pressure, the greater is the tendency to a reestablishment of the arterial lumen. After an insufficiently tightened ligature, not crushing the arterial coats, the reestablishment of the arterial lumen is rapid.

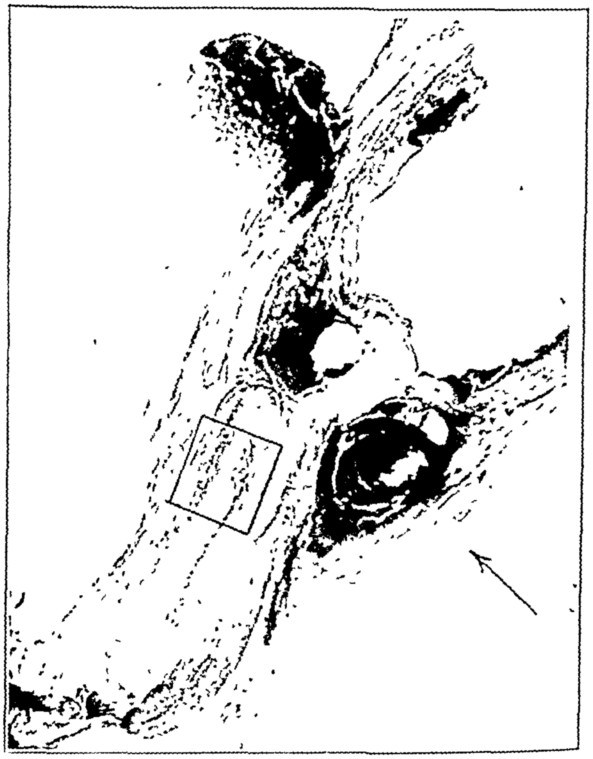

Fig 13.—Longitudinal section of distal ligature of same artery as shown in Figure 11, sixty-four days after operation; magnification about 17 diameters

The process of healing after double or multiple ligatures is essentially the same as after single ligation. In thirty-seven single ligations three arteries had their lumens partially restored, and in fifteen double ligations one artery had reopened.

DOUBLE OR MULTIPLE LIGATIONS WITH SECTION

If an artery is severed between ligatures, the stumps immediately retract and form small conical culdesacs. Within the arterial channel the process of healing is somewhat similar to the healing of arteries after ligation in continuity, though after section the intima of the conical stumps obtains an additional amount of nutrition from the surrounding raw tissue, and the exposed stumps are soon filled with granulation tissue, which forms a plug. Whether the ligature is absorbed, relaxes, or cuts through into the lumen, this cicatricial plug has already sealed the arterial lumen (Figs. 8, 9, 10, 11, 12, 13 and 15). The same process takes place in both the proximal and the distal arterial stumps. This plugging of the exposed ends of the divided artery and original retraction of the stumps, from one to several centimeters from each other, makes the chances of reestablishment of the arterial channel apparently impossible. Sections and careful study of the tissue between these retracted arterial stumps have shown merely connective tissue and no attempt at canaliculization or reestablishment of the lumen (Fig. 14). In twenty-eight multiple ligations with division of the artery there was no instance of even a partial reestablishment of the arterial channel.

SUMMARY

1. In five cases cited there was reestablishment of the arterial lumen following ligation in continuity of a large artery.
2. Eighty single and multiple ligations of brachial, femoral and carotid arteries of dogs with and without section of the artery were done and specimens collected at various intervals from a few hours to seven months after operation.
3. Four of fifty-two ligations in continuity and none of twenty-eight ligations with section were followed by a partial reestablishment of the arterial channel.
4. In multiple ligations with section of the artery the ends retract, and the intima of each stump is exposed to the surrounding raw tissue, securing an additional amount of nutrition and forming a firm, permanent cicatricial plug.

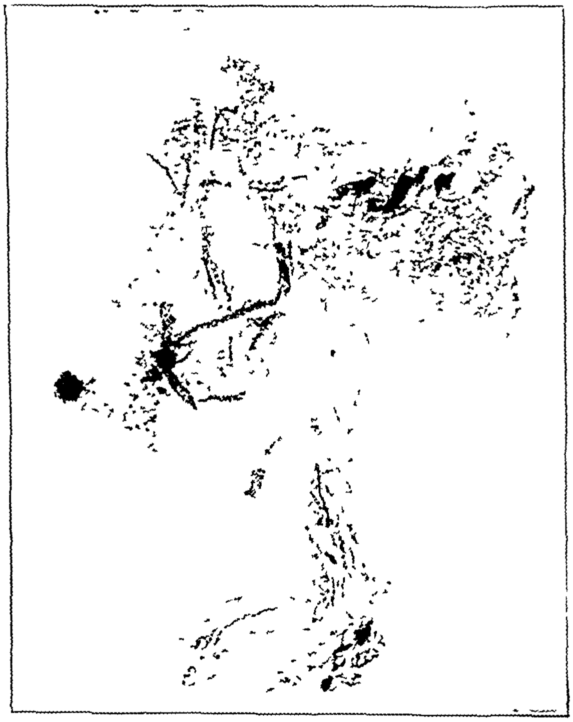

Fig 14—Cross section of tissue between ends of artery shown in Figures 11 and 13 This is connective tissue and does not contain any trace of vessels which could reestablish the original arterial stream; slightly reduced from a photomicrograph with a magnification of 45 diameters.

CONCLUSIONS

The results of these studies indicate that, in order to insure a permanent occlusion of a large arterial channel, the best method of ligation is to apply two or more ligatures and to sever the artery between the ligatures, allowing the ends of the artery to retract. In large vessels it is better to apply three ligatures and to divide the artery between the two distal ligatures. By this procedure the proximal ligature takes up the impulse of the heart beat and permits the tissue within the grasp of the distal ligature to heal at rest.

MELANOSARCOMA OF CHOROID WITH EXTENSION TO ORBIT

REPORT OF CASE *

EDWARD STIEREN, M.D.
PITTSBURGH

In malignancy of the eye and its adnexa, radium used alone or as an adjunct to surgical measures has proved to be of incalculable benefit. Recent writers report prompt and lasting cures from its use.

Aikins [1] speaks of a favorable outcome in two cases of sarcoma of the conjunctiva and one case of inoperable sarcoma of the orbit, as the result of radium treatment. Johnson [2] reports seven cases of carcinoma of the conjunctiva cured with radium emanations, and in his summary states that surgery usually fails to cure and actually assists the local and regional spread of the disease. Francis [3] reports a case of malignant lymphoma of the orbit in which radium was used after the growth had been removed by operation, with no recurrence in three years. Marcotty [4] reported a case of

bilateral lymphadenoma in which radium treatment was followed by prompt improvement. In glioma of the retina, Jacoby[5] reports three cases in which the use of radium is apparently proving of value, and Metzger,[6] who uses the term neuroblastoma, attributes to radium a cure. He makes the sage observation that there is no way of ascertaining macroscopically that the malignant process does not extend beyond the cut end of the optic nerve, and advises the prompt use of radium after every enucleation in this condition.

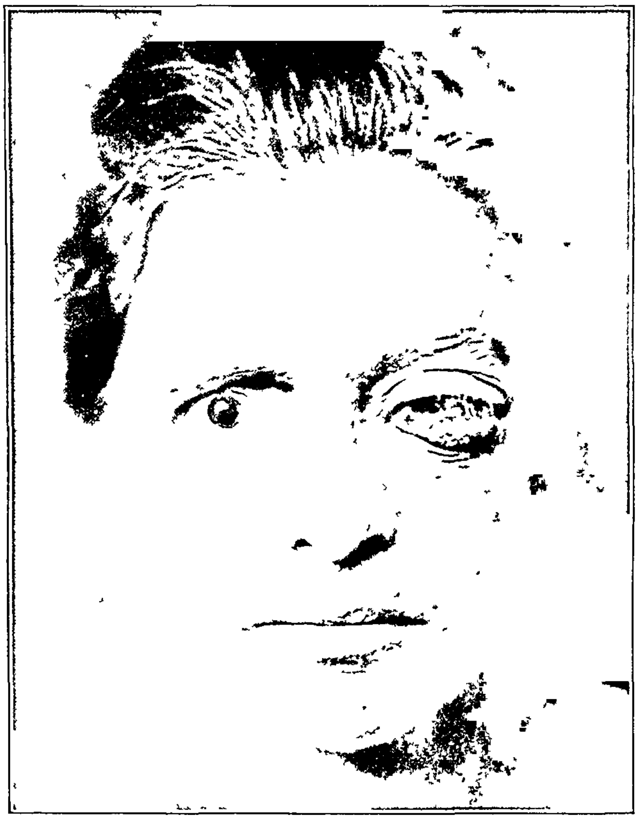

Fig 1 —Enlargement of eyeball and exophthalmos.

D. Y. and J. P. Keith[7] report a case of epithelioma of the cornea, in which the entire cornea was the color of limestone. Under the application of radium for five months, normal vision was obtained, and there was no recurrence nine months later. Wilder's[8] case of melanosarcoma at the limbus showed progress toward a cure under the use of radium.

REPORT OF CASE

Mrs. D. D., aged 40, an Italian, referred by Dr. J. A. Boale, Jan. 26, 1921, had recently had acute pains in the left eye on several occasions, and the eye had been blind for the past three or four months.

The right eye was normal; vision, 6/5; pupil, normal in size and reaction; media, clear and fundus negative; tension, 28 mg. McLean.

The left globe was moderately injected; pupil, dilated; tension, 60 mg. McLean The anterior chamber was shallow and the lens clear. There was a grayish-brown, funnel shaped detachment of the entire retina. The eye did not transilluminate below in an area extending from the external to the internal rectus muscles, but transmitted light through the upper half of the sclera.

A diagnosis of intra-ocular growth was made, and the patient was urged to have the eyeball enucleated at once. This advice was ignored, and the patient was lost sight of until Oct. 3, 1922, twenty months later, when she appeared with the eye proptosed and enlarged, a portion of the sclera below protruding between the lids, and the globe practically fixed in the orbit. A fundus reflex could be obtained in the outer upper quadrant, the remainder of the vitreous chamber being filled with a brown mass. The lower two thirds of the eyeball, including the protruding scleral portion, did not transmit light.

A generous enucleation, including all the apparently involved orbital tissues, was performed the next day, and the tissues were loosely approximated with catgut sutures. A laboratory report of melanosarcoma having been received, two days later, radium needles, 75 mg., were implanted deeply into the orbit, held in place with moist cotton sponges, left in situ five hours As a result, the tissues in the bottom of the orbit became charred, and eventually sloughed out. Healthy granulations followed, and the orbit healed entirely in four months, when a glass eye was inserted, which has been worn with comfort and good cosmetic effect ever since.

There has been no local recurrence or distant metastasis up to the present time.

COMMENT

The use of radium in malignancy, as well as in various benign affections of the eye and its appendages, is far past the experimental stage. Various authorities, notably Ewing,[9] Withers[10] and Lane,[11] have greatly advanced our knowledge of the principles and practice of radium therapy.

ABSTRACT OF DISCUSSION

DR. ARTHUR J. BEDELL, Albany, N. Y.: In a series of forty sarcomas of the choroid, only one showed a definite extension into the orbit. This was in a man, aged 45, who five years before the first examination was said to have had a detachment of his retina resulting from an injury. The left eye was blind and the pupil was irregularly oval, 7.5 mm. The nasal side of the vascular iris was adherent to a cataractous lens, Schiötz 35. The Wassermann reaction was four plus. He had had two courses of arsphenamin. Under physostigmin, tension became normal and the patient was comfortable. Two months later the eyeball became injected, with slight exophthalmos and some limitation of motion in all directions. The eye was enucleated. A large mass was found extending from the globe to the optic foramen. In gross appearance it suggested melanotic sarcoma, and microscopically was found to be of the pigmented spindle cell type. Four months after the operation a nodule was found in the orbit. After a complete exenteration, he was given 1,500 mg. hours of radium. He died twelve days later, after having had a severe pain in his chest. It was impossible to exclude gumma; hence the delay in operation. Dr. Feingold has just given me the history of a 5 year old boy from whom one eye was removed for an intraocular tumor which showed several protuberances like the heads of rivets on the outside of the sclera. The tumor was a leukosarcoma. Dr. R. F. French of Marshalltown, Iowa, has kindly sent me the history of a man, aged 68, whom he observed for ten years. When first seen there was a definite loss in the lower field of the right eye. Three and one-half years later, the tension with the Gradle instrument was 61 and the lens was opaque. He was advised to have the eye trephined, but did not accept the operation for two months. Fifteen months later there was a recurrence of pain, which was controlled by phyosostigmin. About eight years after the first examination, a new growth extended through the sclera and encircled the external rectus muscle. The eye was enucleated and the growth found to be an highly melanotic spindle cell sarcoma involving the entire choroid and extending through the sclera posteriorly. I believe it unwise to depend on radium, and feel that the safest procedure is to give radium before and after operation.

DR. E. C. ELLETT, Memphis, Tenn.: A woman, aged 48, was seen in 1921, having been blind in the left eye for three years. The pupil was dilated and fixed, the lens opaque, tension plus 2, and the eyeball protruded, the exophthalmos amounting to 10 mm. The conjunctival vessels were very large and tortuous, and there were new vessels in the iris. Downward and outward there was a large dark subconjunctival mass (scleral staphyloma) extending from 2 to 6 o'clock. The orbit seemed to be free of any growth, and ocular rotations were limited. Transillumination showed a clear eyeball except where the light was over the dark mass. The eye was removed and the dark mass was found to be part of a growth which had burst through the sclera. All parts of the growth were removed and radium was applied. There has been no recurrence. The tumor was reported to be a fibroblastoma, moderately pigmented (melanosarcoma).

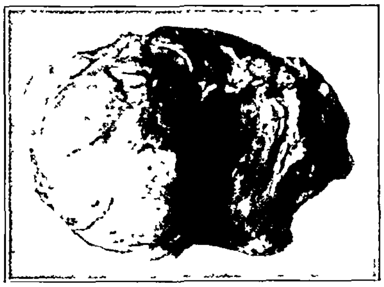

Fig. 3.—Protrusion of sclera and tumor mass.

DR. E. E. BLAAUW, Buffalo: The question of perforation of the bulb and extension into the orbit is not such a rare condition. Enough cases have been reported in the literature. One phase in this process has not been touched on frequently. Well known is the propagation inward of a new growth at the limbus and adjacent region; but when an extensive involvement of the orbit with a rather unimportant development inside the bulb is found, the possibility of a primary extrabulbar origin should be taken into consideration. Ballaban and Mulock Houwer have reported such a condition, and the latter has particularly drawn attention to this development, mentioning that chromatophores are found at the exit of the posterior ciliary nerves and vessels or in nevus of the posterior scleral surface (Axenfeld).

DR. W. H. WILDER, Chicago: If it is proper in this connection, I should like to raise the point that we are too frequently inaccurate in our records of the treatment of these cases by either radium or the roentgen ray. We frequently see reports of cases of treatment of malignant growths with radium in which we are not told how the radium was used, nor whether it was by emanations or radium metal. In communications on this subject the treatment should be more accurately described. If radium emanations were used it should be so stated and the length of time in millicurie hours; but whether metal or emanations are used, the amount, the time, the distance from the growth, and the kind of screen used should all be stated to enable us to arrive at some definite conclusions as to the therapeutic effect of these agents.

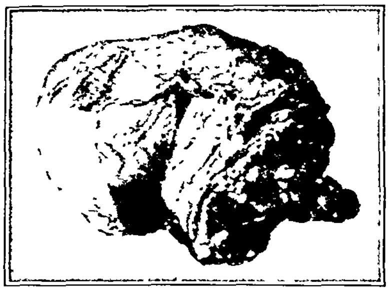

Fig. 4.—Tumor mass extension into the orbit.

DR. EDWARD STIEREN, Pittsburgh: When radium was used in this case, almost three years ago, we knew nothing about millicurie hours or radium hours. We were much in the dark as to what form to use, the time and how much to use. In this case, 75 mg. in needles was implanted for two hours. Now, thanks to the radium workers, we can determine much more accurately just how much to give in these various cases.

DEEP ROENTGEN-RAY EXPOSURE

AS AN AID IN THE DIFFERENTIAL DIAGNOSIS OF MEDIASTINAL TUMORS *

WILLIAM A. EVANS, M.D.
AND
TRAIAN LEUCUTIA, M.D.
Roentgenologist and Resident Roentgenologist, Respectively, Harper Hospital
DETROIT

The accurate diagnosis of mediastinal tumors is closely connected with the discovery and development of the science of roentgenology. A review of the literature previous to the diagnostic application of the roentgen ray reveals that the clinical diagnosis of mediastinal tumors, and especially their differentiation from lung tumors, was a rare occurrence. Indeed, all the reports, starting with Morgagni's[1] first description of an ulcus cancrosum of the lung in 1708, and continuing as far as Hare's[2] treatise on affections of the mediastinum, in 1889, were based on gross pathologic findings, and only since 1871 (Langhans[3]) have they been based also on the microscopic findings; but in all instances the clinical diagnosis of the disease remained vague and uncertain. The similarity of the symptom complex of mediastinal tumors and of lung lesions made the problem especially difficult. Since Hare's work, however, the interest in the subject has grown to such an extent and the literature has become so extensive that Christian,[4] in 1902, was able to collect reports of a hundred cases of sarcoma of the mediastinum and in 1912 Adler [5] could tabulate 374 cases of carcinoma and ninety cases of sarcoma of the lung. Nevertheless, the methods available for the clinical diagnosis were even at that time inadequate, and, as Wessler and Jaches [6] remark, "The diagnosis of mediastinal tumor was considered a brilliant accomplishment and a clinical *tour de force*." A new method of examination was more than hoped for. Adler himself writes with regard to this, "X-rays have become a most remarkable and efficient aid to diagnosis in general . . . and there exists a well founded hope . . . that with the systematic and proper application of rays to the exploration of the chest the diagnosis may be assured, when no other means will give equally certain results."

---

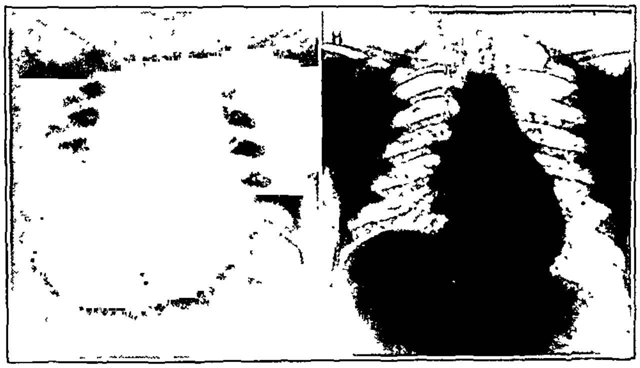
[3] Langhans, T.: Primärer Krebs der Trachen and Bronchien, Virchows Arch. f. path. Anat., 1871, p. 53.

Since that time many well known roentgenologists, such as Baker,[7] McMahon and Carman,[8] Barjou,[9] Christie,[10] DeWitt,[11] Kahn,[12] Childs,[13] Hall,[14] Rowe,[15] Gaarde,[16] Kahn and Sloan,[17] LeWald [18] and others have brought the method of the roentgenologic examination of the chest to such perfection that the diagnosis of mediastinal tumor now can be made with certainty in the majority of cases. Furthermore, by combining the radiologic examination with a thorough clinical examination,[19] laboratory tests, bronchoscopy and—if necessary—esophagoscopy, certain conclusions can be drawn also with regard to the type and nature of the tumor. Thus, inflammatory conditions, such as acute mediastinitis, mediastinal abscess, tuberculosis, and syphilis of the mediastinum or aneurysm of the aorta and great vessels in the majority of the cases can easily be differentiated from the true neoplastic tumors. But there still remains the problem of differentiating the true neoplasms among themselves, especially since they form the majority of the pathologic processes occurring within the mediastinum. If there is extension of the new growth to the regional lymph glands or some remote part of the body, biopsy can be performed and the diagnosis thus established. However, if the lesion is localized to the mediastinum itself, often all available methods will fail to reveal the true type of the tumor. In consequence, no accurate plan of treatment can be determined, especially with regard to whether radiation therapy should be used or whether the very dangerous procedure of thoracic surgery should be undertaken.



A B

Fig. 1.—*A*, large lymphosarcoma of the mediastinum, producing marked pressure symptoms; *B*, ten days following roentgen-ray exposure, the lesion has entirely disappeared.

In studying the radiosensitivity of the different normal and pathologic cells toward radiation, we have tried to find whether or not the selective action of the roentgen rays on the different cells could be used as an index of the type of tumor irradiated; this would enable us to form conclusions with regard to the nature of the different mediastinal tumors. Fortunately enough, the mediastinum contains tissues that give rise to tumors occupying positions far apart in the large scale of radiosensitivity of the cells. In administering a standard quantity of radiation over these tumors, because of the different response, there will be a variation in the reduction of the size of the tumor in the time unit. This we are able to measure.

TECHNIC

The following is our technic: After the presence of mediastinal tumor by the methods enumerated above is established and the possibility of an inflammatory condition is excluded as far as possible, we first take a roentgenogram of the chest in a standard position, using a standard technic (the usual short time exposure at 40 inches distance). Then we administer a homogeneous dose of from 90 to 100 per cent. skin unit dose over the tumor mass by using rays of short wave length (in our case 0.137 Angström unit, obtained by a current of 200,000 volts and by a filtration of 1 mm. of copper and 1 mm. of aluminum). We have chosen from 90 to 100 per cent. skin unit dose because this is the optimum dose for the majority of tumors, and therefore it acts at the same time as a treatment dose. Following the exposure, we take, by using the standard factors, check-up plates at different intervals; namely, ten days, three weeks, six weeks, and thereafter at intervals of three months, and we compare the size of the tumor on each of these plates with the size of the tumor on the original plate. The rate and amount of reduction in the size of the mass will be different according to the type of the tumor. Of course, we realize that while the decrease in the size of the growth is the direct result of the effect of the rays on the tumor cells themselves, there are other factors, such as local tissue reaction, or increase or decrease in the general resistance mechanism of the organism, that may accelerate or retard the reduction of the mass. However, as stated above, the mediastinal tumors originate from cells of such widely different radiosensitiveness that, in attempting to differentiate them, the changes produced by the secondary reaction may be neglected. For the same reason, we do not attempt to calculate the reduction in the size of the tumor in mathematical figures, but merely content ourselves with expressing it in the arbitrary form of biologic response.

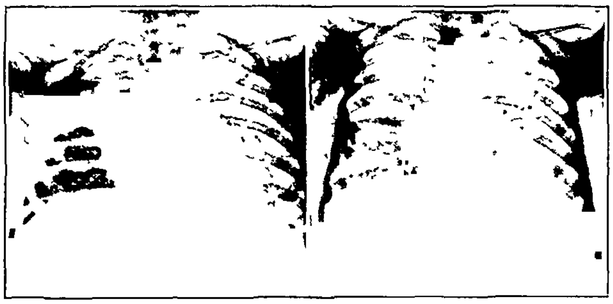

Fig. 2.—*A*, mediastinal involvement in lymphatic leukemia; *B*, ten days following roentgen-exposure, the lesion has entirely disappeared.

TYPES OF TUMORS

In studying mediastinal tumors from a pathologic standpoint, we find that they are primary or secondary. The diagnosis of secondary mediastinal tumors as a rule causes no difficulty, because they are of the same nature as the mother tumors. The primary tumors of the mediastinum may originate in the lymph nodes, connective tissue, thymus or the thyroid gland. They may be benign (fibroma, adenoma, lipoma, chondroma, myoma, neuroma, etc.) or malignant. The malignant tumors may be:

1 Lymphomas (lymphosarcoma, pseudoleukemia, lymphatic leukemia, Hodgkin's disease).
2 Sarcomas, originating from the areolar connective tissue (fibrosarcoma, spindle cell sarcoma, alveolar cell sarcoma, etc.).
3 Carcinomas, mostly of thymic or thyroid origin.
4. Dermoid cysts and teratomas.

According to their occurrence, the most common primary mediastinal tumors are those originating in the lymph glands (malignant lymphomas). Second to these in frequency are the sarcomas of the areolar connective tissue and carcinomas, especially those of thymic origin, since many consider the sarcomas of the thymus of epithelial origin and place them among carcinomas. Dermoid cysts and solid teratomas are rare. Smith and Stone[20] could collect reports of only 125 cases in the whole literature. Benign tumors of the mediastinum are exceedingly rare.

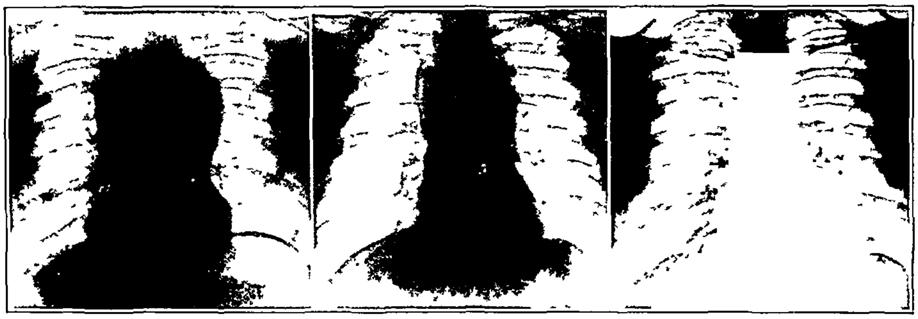

Fig 3.—*A*, Hodgkin's disease, with the mediastinal manifestation only; *B*, ten days following roentgen-ray exposure, the tumor has reduced to about one half of the original size; *C*, six weeks following roentgen-ray exposure, the tumor has entirely disappeared.

In explaining the response of these different tumors toward radiation, we find that the general laws of cellular radiosensitivity hold good:

1. The more embryonal and undifferentiated the type of the cells, the greater the response to radiation (Tribondeau-Bergonié law).
2. Dividing mytotic cells are from eight to fifteen times more vulnerable than when at rest (Mottram).
3. Hyperchromatic cells are more sensitive than cells poor in chromatin.
4. Tumors rich in paraplastic structures are more resistant to radiation than cellular tumors.
5. Tumors well supplied with blood and lymph vessels respond more readily to radiation than tumors consisting of solid cell masses.

In accordance with these laws, mediastinal tumors originating from the lymph nodes will respond best to radiation, and tumors originating from the proliferation of the lymphocytic element will respond more readily than tumors originating from the proliferation of the reticulo-endothelial cell element. Benign tumors, on the other hand, because of their mature adult type, will show little or no response to radiation. Sarcomas, carcinomas and teratomas will occupy an intermediate position. There will be a more or less pronounced initial response, but later, unless further exposures are given, recurrence of the disease will follow.

RULES FOR TREATMENT

In practice, we believe we can establish the following rules:

1. Tumors originating from the proliferation of the lymphocytic cell element of the mediastinal lymph glands or of the thymus, such as lymphosarcomas, thymomas (usually lymphosarcomas), pseudoleukemia, lymphatic leukemia and simple lymphomas, entirely disappear within from four to ten days following the administration of from 90 to 100 per cent. skin unit dose of roentgen rays over the tumor mass. If there is no further extension of the disease at the time of the treatment, patients will remain well; but if the lesion has already microscopically invaded other parts or organs of the body, later new manifestations of the disease occur and the patients may die as a result of these manifestations. In no instance have we seen a local recurrence in the group of tumors mentioned, if the lesion once had disappeared.

Figure 1 *A* shows a very extensive lymphosarcoma of the mediastinum, producing marked pressure symptoms, with resulting edema of the face and very marked dyspnea. The condition of the patient was so grave that oxygen inhalation had to be administered during the time of the roentgen-ray exposure. Figure 1 *B* shows the condition ten days following the exposure, when the lesion had entirely disappeared. Later there was extension of the disease to other parts of the body, so that the diagnosis could be confirmed by biopsy; but the

---

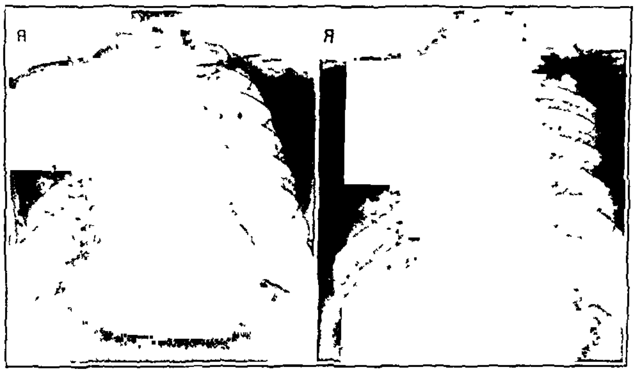
20. Smith, L W., and Stone, J. S.: Tumors of Mediastinum in Children, Ann. Surg. 79: 687-709 (May) 1924.

mediastinum remained clear. Figure 2 shows a case of mediastinal involvement in lymphatic leukemia. The mediastinum cleared up within ten days following the roentgen-ray exposures.

The further differentiation of these various lymphatic tumors is based on clinical and laboratory examination. Simple lymphoma is slow growing and of benign character. A thymoma—especially in the early stage—is located in the upper mediastinum and forms a pyramid capping the pericardium. A blood count will clear up the origin of the mediastinal involvement in case of lymphatic leukemia. The mediastinal manifestation of pseudoleukemia, especially if localized to this one region, cannot be accurately differentiated from lymphosarcoma, but the pathologic affinity and the clinical course of these two diseases are so closely similar that many authors regard them as manifestations of the same disease.

2. Tumors originating from the proliferation of the reticulo-endothelial cell element of the mediastinal lymph glands (Hodgkin's disease, Sternberg's type of hyperplastic tuberculosis, or pure endothelioma) will reduce within ten days following the treatment to about half of the original size, and will entirely disappear within from five to six weeks following the exposure.

Figure 3 *A* shows a mediastinal tumor, which was the only manifestation of a Hodgkin's disease. A clinical or roentgenologic differentiation from lymphosarcoma was impossible. The patient had the symptom complex of localized mediastinal tumor, and his condition was so grave that oxygen inhalation had to be administered during the roentgen-ray exposure. Figure 3 *B* shows the entire disappearance of the lesion, six weeks following treatment. Later there was extension to the supraclavicular glands (Fig. 3 *C*), but this also was successfully treated and the patient has remained well for a period of almost three years.



A B

Fig. 4.—A, aneurysm simulating mediastinal tumor; B, nine months following roentgen-ray exposure, the tumor remained uninfluenced by radiation.

Sternberg's type of hyperplastic tuberculosis shows the same response toward radiation, but, as a rule, there is a multiple involvement of the glands, so that a clinical or pathologic differentiation is possible. Endotheliomas of the mediastinum are exceedingly rare.

3. Other primary malignant tumors of the mediastinum, such as sarcomas originating from the areolar connective tissue (fibrosarcoma, large round cell sarcoma, alveolar cell sarcoma, etc.), or carcinomas or teratomas show a more or less pronounced reduction in size following the administration of a 90 to 100 per cent. skin unit dose, but they rarely disappear at the period of six weeks following exposure. In such cases the irradiation aids us in establishing the fact that we are dealing with a malignant tumor, but no accurate diagnosis can be made with regard to the type of the tumor.

4. Benign tumors of the mediastinum (lipoma, chondroma, fibroma, adenoma, myoma, neuroma, dermoid cysts, etc.), or pseudotumors (aneurysm, encysted pleural effusion or chronic abscess) remain uninfluenced by roentgen-ray exposure. Except for aneurysm, which can be excluded by clinical examination, surgical intervention is indicated in these cases. Therefore, a preliminary trial exposure in order to eliminate malignancies is of great importance.

Figure 4 *A* shows an upper mediastinal tumor that was first thought to be a sarcoma (probably lymphosarcoma). One hundred per cent. skin unit dose of radiation was administered over the tumor in order to test its radiosensitivity. Plates taken six weeks, three months and again nine months later (Fig. 4 *B*) fail to reveal any change in the size of the tumor. In consequence, a diagnosis of aneurysm with bronchostenosis[21] due to pressure was made.

CONCLUSIONS

The variation in the sensitivity of the different tumor cells toward radiation, usually given for therapeutic purposes, enables us to draw certain conclusions with regard to the type of tumor, in case no accurate clinical or pathologic diagnosis can be made.

In administering a standard quantity of radiation over different growths, there will be, because of the selective action of the rays, a variation in the reduction of the size of the tumors in the time unit, which we are able to measure. According to the rate of reduction, we are able to classify the mediastinal tumors in the following groups:

1. Tumors originating from the proliferation of the lymphocytic cell element of the mediastinal lymph glands or of the thymus (such as lymphosarcomas, thymomas, pseudoleukemia, lymphatic leukemia and simple lymphomas). These tumors entirely disappear within four to ten days following the administration of a 90 to 100 per cent. skin unit standard dose of roentgen rays over the tumor mass.

2. Tumors originating from the proliferation of the reticulo-endothelial cell element of the mediastinal lymph glands and thymus (Hodgkin's disease, Sternberg's type of hyperplastic tuberculosis, endothelioma). These tumors are reduced within ten days following the administration of a 90 to 100 per cent. skin unit dose to about one half their original size, and then entirely disappear within six weeks following the exposure.

3. Other primary tumors of the mediastinum, such as sarcomas, originating from the areolar connective tissue (fibrosarcoma, large round cell sarcoma, alveolar cell sarcoma, carcinoma of the thymus or thyroid glands and teratomas). These tumors show a more or less pronounced reduction in size following the administration of the 90 to 100 per cent. standard skin unit dose, but they rarely disappear at the period of six weeks following exposure. In such cases, the radiation helps us in establishing the fact that we are dealing with a malignant tumor, but no accurate diagnosis can be made with regard to the type of tumor.

4. Benign tumors of the mediastinum (lipoma, chondroma, fibroma, adenoma, myoma, neuroma, dermoid

cysts, etc.) or pseudotumors (aneurysm and encysted pleural effusion, chronic abscess). These tumors are very little or not at all influenced by radiation.

A further differentiation of the tumors of the foregoing groups is possible in the majority of instances by clinical or laboratory examination except for Group 4, in which surgical intervention is indicated.

ABSTRACT OF DISCUSSION

DR. E. C. ERNST, St. Louis: Mediastinal tumors are not infrequently almost impossible of correct diagnosis, even though every conceivable clinical and the usual laboratory aid have been taken advantage of. Under such circumstances, the roentgen ray occasionally proves valuable, diagnostically and therapeutically. Mediastinal pathologic changes do not always present characteristic fluoroscopic visualizations; in fact, the many noncharacteristic variations of the outline of these shadows have been our chief diagnostic handicap in difficult and doubtful cases. In these cases, we employed rather mild dosage, but we soon found out that this was an error. I am glad to hear Dr. Evans state that he gives rather large doses. I did not understand whether he gave this dose at one sitting or distributed it over a period of four or five days or a week. We have followed the plan of spreading it over a period of a week. We have had a considerable number of recurrences, and rather than seeing the patient only after six months, we insist on seeing him also at nine and twelve months and a year and a half and two years.

DR. WILLIAM A. EVANS, Detroit: The practical application of the information contained in this paper depends on the variation in the response of the tumors to irradiation and on the variable amount of irradiation needed in the proper treatment of the various types of thoracic tumors. For instance, lymphosarcoma apparently is controlled by one series of treatment, whereas those tumors that respond more slowly, as of the type found in Hodgkin's disease, require two series, and the more resistant types of tumors require several series for their proper control At the present time we are using a water cooled tube, and the treatments are all administered within one week In lymphosarcoma and Hodgkin's disease, all of the lymphatic groups are treated, so that some patients are treated through as many as eighteen or twenty portals. When repetition of the treatment is indicated, the second series is given about ten weeks after the first. Each group of glands receives approximately a 90 per cent. depth dose.

Filtrable Viruses.—The term "filtrable virus" implies that the common property of the ultramicroscopic organisms is filtrability through a candle already proved impervious to ordinary small microbes. When the vesicular fluid of a vesicle in foot-and-mouth disease is taken and largely diluted—for example, 0.2 c.c. with from 30 to 50 c.c. of saline solution —and the mixture is filtered through a candle, the infective agent passes through apparently without loss. This fact, discovered by Loeffler and Frosch twenty-seven years ago, was the first definite "filtrable" virus; it still influences the bacteriologist to such an extent that filtrability is regarded as the final test of an invisible virus. The contents of a herpetic vesicle may be diluted with saline solution, filtered, and the filtrate is infective, as is determined by its power to cause pathologic changes in the brain of the rabbit. If, however, infective brain tissue be taken from a rabbit ill with, or dead of, herpetic encephalitis, and the tissue be ground thoroughly with sand, diluted with saline solution, filtered through sand (or spun) to remove coarse particles, and then passed through a fine candle, the final filtrate is noninfective. Here we can only conclude that the virus has become so firmly attached to brain tissue that it is not possible to separate them by ordinary mechanical processes Filtration, in other words, breaks down. Again, calf lymph which undoubtedly contains the virus of vaccinia may be filtered, but the filtrate does not contain the virus—Gye, W. E.: *Brit. M. J.* **2**:189 (Aug 1) 1925.

Clinical Notes, Suggestions and New Instruments

CARCINOMA IN AN ABERRANT THYROID AT BASE OF TONGUE

ASTLEY P. C. ASHHURST, M.D., AND C. Y. WHITE, M.D.,
PHILADELPHIA
Surgeon and Director of Laboratories, Respectively,
Episcopal Hospital

Aberrant thyroid tissue in the tongue is unusual. Carcinoma occurring in such an aberrant thyroid is almost unknown. Bérard and Dunet[1] state that there is not yet on record a proved case of cancer of a lingual thyroid. The following is the history and pathologic report of such a case:

REPORT OF CASE

A. C., a man, aged 56, admitted to the Episcopal Hospital, Nov. 22, 1916, complained of a lump on the back of his tongue near the right lower molar teeth. This lump had been noticed for more than twenty years; first as a small hard mass that very gradually grew larger. After about five years, it began to give him pain. Thirteen years previous to his admission to the Episcopal Hospital (i. e., in 1903), this mass had been removed at the Methodist Hospital, Philadelphia, by Dr. Walter Roberts, who reported to us that it was thought to have arisen in the lingual tonsil, and that microscopic examination had shown it to be entirely benign. Unfortunately, neither the sections nor the detailed report of the examination had been preserved.

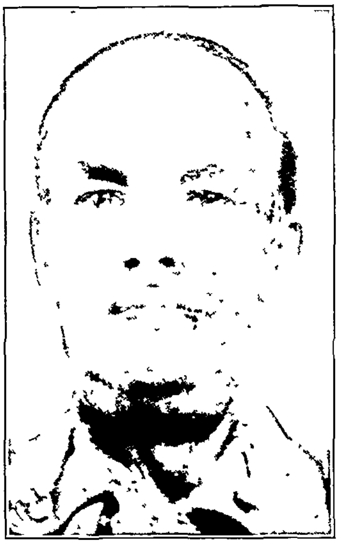

Fig 1.—Nine days after excision (electric cautery) of tumor growing from right base of tongue (carcinoma of aberrant thyroid).

The patient stated that about three years after this operation, he noticed the glands beneath the jaw increasing in size, first on the right side of the neck, later on the left side; the growth on the tongue gradually returned. He then came to the hospital, on account of difficulty in eating and swallowing, and pain in the tongue.

The mass was about 8 cm. long in its anteroposterior diameter, on the right side of the tongue involving its posterior half; its posterior border, close to the epiglottis, was raised 2.5 cm. from the base of the tongue, but its anterior border was not so high. The tumor extended laterally as far as the alveolus, but not beyond the midline. It was slightly ulcerated on its surface, was almost of wooden consistency, and was continuous with a mass in the floor of the mouth. The latter mass felt cystic. The submaxillary salivary glands and lymph nodes on both sides of the neck were visibly enlarged (Fig. 1) and were firmly attached to the deeper structures. The lower cervical lymph nodes were palpable, and they, as well as the epitrochlear, femoral, inguinal and iliac lymph nodes on both sides of the body, seemed larger than normal.

The tumor was evidently inoperable, with any hope of curing the patient, but his condition grew steadily worse while in the ward; on some days it was impossible for him to swallow. He had an evening rise of temperature to 100 F., and his white blood cells numbered from 15,000 to 19,000 on several occasions. It was finally determined to burn off the part of the tumor projecting above the tongue.

---

[1] Bérard and Dunet: Cancer of the Thyroid, Paris, 1924, p. 454.

Operation was undertaken, December 12, with a tentative diagnosis of lymphoma of the lingual tonsil. Under intratracheal ether anesthesia, the lump was burned off the tongue by the electric cautery knife. Its base was almost of cartilaginous hardness. No bleeding occurred. Nothing was done to the mass in the floor of the mouth or to the submaxillary masses.

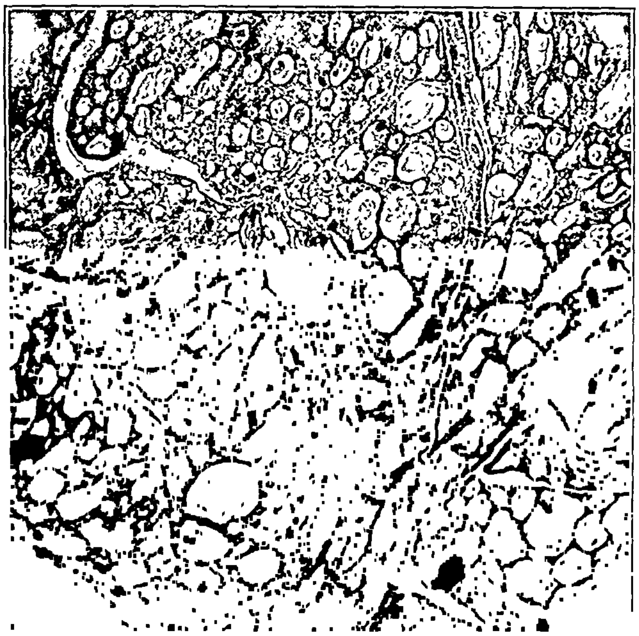

Fig. 2.—Lingual thyroid, showing carcinoma in other areas.

The patient improved rapidly after operation. His fever disappeared; he was free from pain and was able to swallow easily. The masses in his neck grew much smaller, and in less than two weeks they had contracted so much that wrinkles began to appear in the skin of the neck. He was kept under observation for several months, and continued to do well. Eventually, efforts to find him were ineffectual, and though no record of his death can be found in the vital statistics of the city of Philadelphia, it is not probable that he is still living.

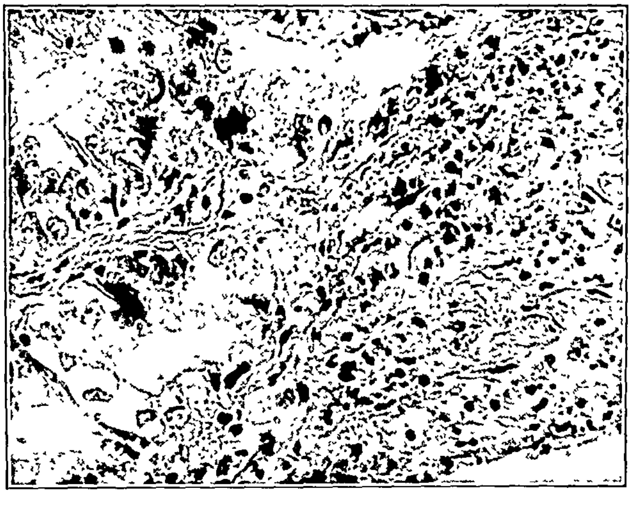

Fig. 3.—Carcinoma in lingual thyroid.

The pathologic report showed that the sections of the tumor from the tongue contained lobulated areas of typical thyroid tissue (Fig. 2), which in places almost bordered the epithelial surface of the tumor. There was a very small amount of connective tissue framework in the thyroid areas, yet more than in the normal thyroid. At one point in the section the epithelial covering was deficient, probably from ulceration.

In certain areas of the section, running from typical lobules of thyroid tissue, were dense accumulations of epithelial cells, placed in bands or cords; and in still other areas there was a tendency to alveolar arrangement, that is, an arrangement typical of adenocarcinoma (Fig. 3). In other parts this carcinomatous arrangement was marked by increase of fibrous tissue, separating the epithelial cells into distinct cancer nests, with somewhat the appearance of scirrhous carcinoma. The carcinomatous areas bordered directly the epithelial covering of the tumor, causing thinning of the layers at certain points. The diagnosis was adenocarcinoma of the lingual thyroid.

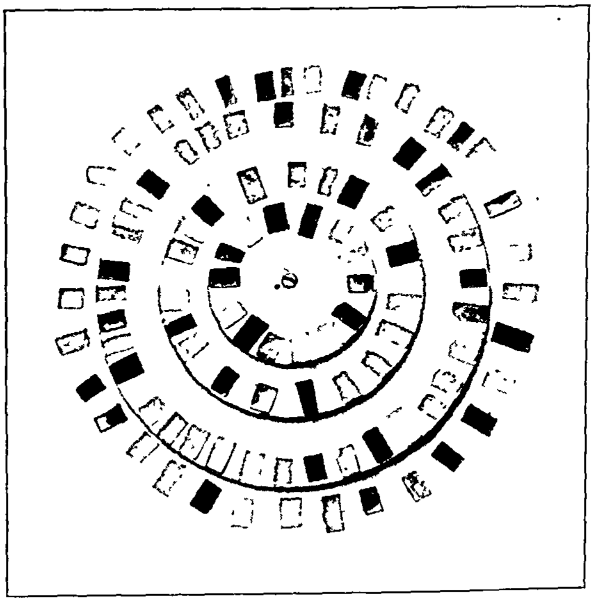
A NEW DEVICE FOR TESTING THE COLOR SENSE

Walter G. Nelson, M.D., Boston

For the last five years, part of my duties has been the examination of the color sense of applicants for various government services. Williams' lantern and the color skeins have both been employed and are still used. However, I have felt that the color skeins have certain disadvantages; among them, the length of time involved in giving the test, the fact that the loose skeins are apt to be misplaced or lost and also the fact that they are apt to become soiled, thus further confusing the applicant.



Color wheel for testing color sense.

About two and a half years ago, I devised a scheme that I think has all the advantages of the color skein system without most of the disadvantages. I have termed the test the "color wheel test," because of its construction. The device has compactness, being 15 inches square and about 2 inches high at its highest point. It also has permanency, for it is constructed of strong, though thin, wood. Metal could be used as well.

On the base are arranged three wheels, one above the other, decreasing in size. On the base and on each wheel are arranged small rectangles of colors in both primary and intermediate shades.

The base and wheels are covered with white enamel, which permits of washing when soiled. The colors are also of washable paint and can be cleansed at will, with a damp cloth.

With this arrangement any given color can be matched simply by turning the wheels; when an applicant performs the task correctly, there will be four colored rectangles in a row, all of the same color, but possibly of lighter or darker shades. If the test is not performed correctly, there will be a confusion of colors.

The person being tested can be required to enumerate each color in order, to name certain colors picked by the examiner, or to pick out all the shades of a given color. The color wheel can also be used to instruct applicants in colors, if they are merely color ignorant and not color blind.

It has been found from frequent examinations, in conjunction with the other tests, that color blindness can be successfully detected by this device. The applicant can see at a glance all the colors, and a great amount of time thus can be saved. The device is compact, and the colors cannot be lost.

If desired, small colored silk or wool skeins can be substituted for the paint colors.

Custom House

SPONTANEOUS SUBCUTANEOUS RUPTURE OF THE TRACHEA

J. W. Nixon, M.D., San Antonio, Texas

No mention is made of spontaneous subcutaneous rupture of the trachea in any of the standard textbooks on surgery, and a study of the literature discloses the infrequency of the condition. Therefore, this case seems to be of sufficient interest to warrant reporting.

M. H., a negress, aged 27, married, while waiting on the table, suddenly experienced a sharp pain in the region of the trachea. She immediately noticed difficulty in breathing, which rapidly grew worse. At the same time, her throat began increasing in size, growing larger with each breath. She was taken to the Robert B. Green Memorial Hospital, where I saw her thirty minutes after the onset of her trouble. On first sight, she appeared to have a large goiter occupying the entire space from the tip of the chin to the manubrium sterni. However, on examination, the tumor was soft and emphysematous, and felt very much like an air cushion. This mass became larger during expiration and smaller during inspiration. At this stage, the patient was breathing with much more difficulty and seemed to be in great distress. The difficulty of breathing was relieved considerably a few minutes later when the skin, which had become extremely tense, ruptured at a point posterior to the angle of the right jaw, anterior to the sternomastoid muscle. A second rupture occurred on the under surface of the arm 2 inches from the axilla, and still another, the third, appeared within five minutes' time at the lower posterior border of the axillary space. At this time, the patient was literally breathing through these three openings in the skin.

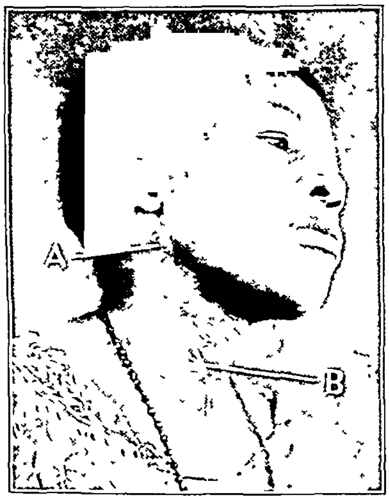


Fig. 1.—First rupture (*A*) and site of operation (*B*).

An operation was performed, Feb. 19, 1925, under ether anesthesia. With the idea of locating the site of the rupture, Dr. A. F. Clark was asked to make a bronchoscopic examination. This was done, but because of the hemorrhage in the trachea, it was impossible to locate the rupture by this method. An incision was then made, exposing the entire cervical portion of the trachea. This part of the trachea was found intact. A bloody froth was seen to be coming up from beneath the sternum, indicating a rupture within the thoracic cavity. Because of the patient's condition, a further exploration was not deemed advisable and a low tracheotomy was performed.

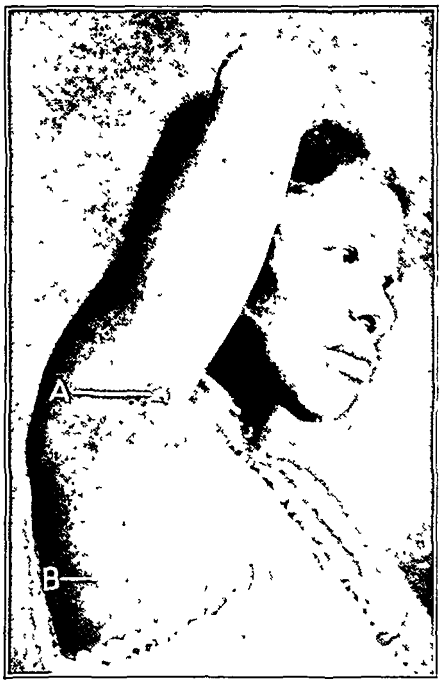

Fig 2.—Second (*A*) and third (*B*) ruptures

During the week following the operation, the patient had an elevation of temperature above normal, the highest being 102 F. The emphysematous condition, which had extended over the neck, right arm, the entire chest and the right axilla, had entirely disappeared at the end of fourteen days. However, a troublesome cough lasted for two months A blood Wassermann test, taken before her departure from the hospital, was negative.

Zeuch, in 1922, made an exhaustive study of the literature, and tabulated all the cases of subcutaneous rupture of the trachea which had been reported up to that time. Only fifty-three cases could be found. It is interesting to know that of all the fifty-three cases mentioned by Zeuch, in every case with the exception of three the rupture was caused by a blow or a violent strain on the trachea. These three cases, together with my own, make a total of four cases occurring spontaneously. This patient had had a cough a few days prior to the rupture, but at the time it occurred, she was not coughing.

The chief point of interest in connection with this case is the need of immediate treatment and the method of so doing. As soon as the diagnosis is certain, an incision should be made through the skin in the midline over the trachea. This should be done without waiting for an anesthetic. Zeuch calls attention to the importance of this procedure, and in my own case the immediate relief the patient obtained following the rupture of the skin in the three places mentioned clearly demonstrates the value of early relief from the pressure caused by the escape of air into the subcutaneous tissues.

AN IMPROVED APPLICATION OF THE USE OF RENAL FLUOROSCOPY AT THE OPERATING TABLE

B H. Hager, M.D., Madison, Wis.
Urologist, State of Wisconsin General Hospital

The application of fluoroscopy at the operating table is now conceded to be an essential prerequisite to successful surgery for renal lithiasis.

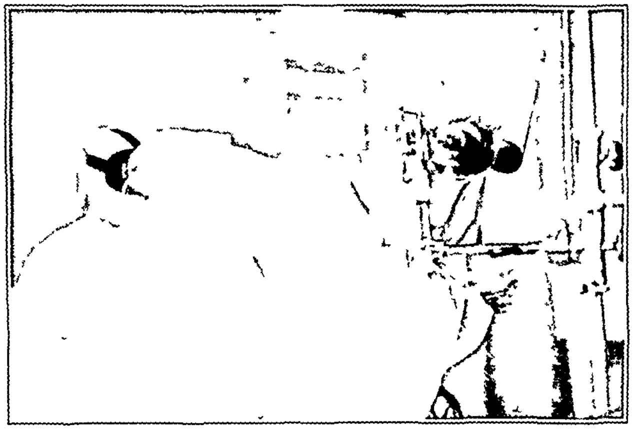

Fig. 1 —Head operating fluoroscope in use.

Braasch, in 1919, was the first to stress this principle, which has since been modified by various surgeons to meet their particular needs By preference, some continue to use the roentgen-ray film rather than the fluoroscope. Without considering the virtues and advantages of either method, the suggestion presented here offers an advantage over fluoroscopy, which entails the presence of a radiologist The roentgen-ray apparatus in use is a modern bedside unit with a 10 ma. Coolidge radiator tube, using a 5 ma. current.

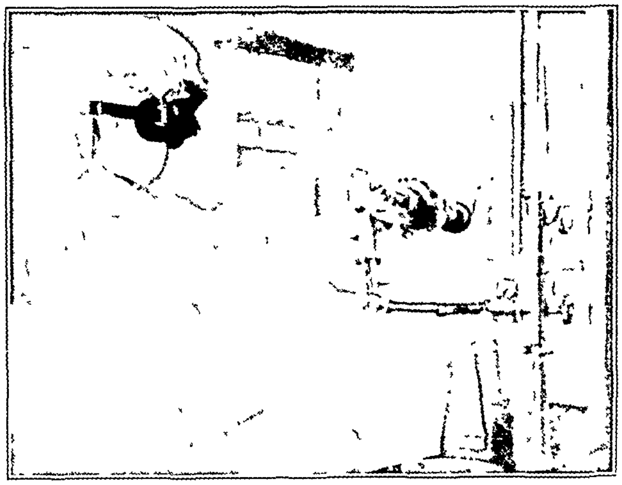

Fig 2 —The nose of the hood of the fluoroscope can be folded back, if accommodation is slow

The accompanying illustrations show the principles of its application. As soon as renal exposure has been obtained, a nurse slips the Patterson head operating fluoroscope over the surgeon's head, a sterile cover having been slipped over the nose of the fluoroscope The time required for accommodation is surprisingly short, much less than is usually anticipated. In persons in whom accommodation is slow, the nose of the hood can be folded back, as shown A colored glass protects the eyes from daylight and allows sufficient light for the surgeon to carry on his work As soon as accommodation occurs, the hood can be extended and the fluoroscopic search for stone begun The method is simple, and does not interfere with surgical asepsis; it allows the surgeon to localize the stone in the kidney with his fingers, and to regulate the roentgen-ray current with the foot switch.

A NEW OBSTETRIC VAGINAL SPECULUM

C O. McCormick, M.D., Indianapolis
Associate, Obstetrical Department, Indiana University School of Medicine

In making immediate postdelivery examinations and repair work, I have for the last two years used a vaginal speculum, designed by myself, which I have found to possess a practical value that warrants its recommendation.

All vaginal specula and retractors that had previously come into my hand were, with one exception, designed and constructed for gynecologic use. It occurred to me that there should be a marked distinction in the design of gynecologic and obstetric specula. At a postdelivery examination, the speculum or retractor should be an instrument that will permit spacious exposure and at the same time be as nontraumatizing as possible, because one is dealing with tissues that have already undergone a large degree of traumatization.

With these two points in mind, I had the instrument made that is shown in Figure 1. It might be spoken of as a modified ribbon retractor, the short, or retractor arm, being thin, wide and flexible (Fig. 2). The length of the short arm is 10.5 cm and its width, 3.7 cm. The length of the long arm, or handle, is 23.5 cm. The rounded, thickened end of the short arm and the turned edges and flexibility reduce tissue injury to a minimum. These protective features and ease of cleanliness are not afforded by the only other obstetric speculum with which I am familiar; namely, that of De Lee.

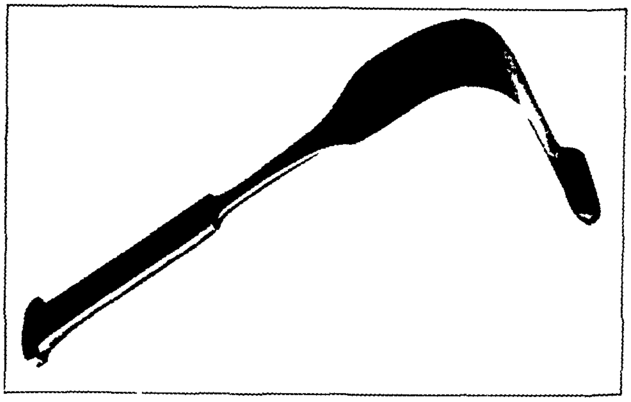

Fig 1.—Obstetric vaginal speculum.

To be used to the best advantage one should, of course, employ two of the specula, thus obtaining counterretraction. I have thus found them to be an excellent aid in exploring or repairing the cervix, and in repairing vaginal lacerations, regardless of how high, because they lend unusual exposure and make repair possible under direct vision. They are, likewise, applicable for perineal and episiotomy repair. If the *episiotomy is mediolateral, or the vaginal laceration lateral,* I have found it desirable to use the instrument on the side of the episiotomy or laceration with a retractor arm of 3 cm. width.

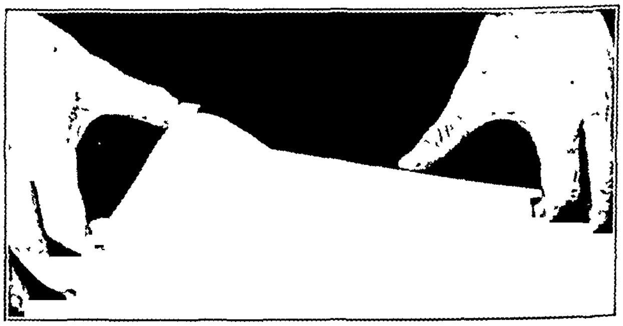

Fig. 2.—Short arm of obstetric vaginal speculum.

REPORT OF COMMITTEE ON VISUAL STANDARDS FOR DRIVERS OF MOTOR VEHICLES *

Acting on the request of the section that the standards submitted last year be modified, your committee has carefully considered the criticisms and suggestions offered and desires to submit the following, hoping it may meet with the section's approval:

(*b*) The applicant has vision of at least 20/50 in one eye and vision of at least 20/100 in the other eye, with or without glasses. Applicants with less vision than 20/100 in the poorer eye may, under certain conditions, be qualified by a special or county board. (See below.)

(*c*) Double vision shall disqualify.

SPECIAL OR COUNTY BOARDS OF PHYSICAL LICENSURE

In each state there shall be a board of physical licensure in each county, or one for several counties, consisting of two general practitioners or surgeons, and one ophthalmologist, which shall meet at stated intervals and have final decision in all cases. These boards so constituted shall be empowered (1) to examine all persons applying to them for a physical license, (2) to pass on the fitness of candidates regarding whose qualifications any individual examiner may be in doubt, and (3) may, under certain conditions, qualify candidates who lack the visual requirements specified above; viz., applicants with a lower standard of vision than 20/100 in the poorer eye, may be qualified by them provided that the vision in the best eye is at least 20/30, without the aid of glasses, and the field of vision is normal, that hearing is normal in both ears, and that the applicant is fully capacitated in all other respects physically, and alert mentally. In such cases applicants with one eye partially or wholly blind, or even entirely absent, may be qualified. These boards shall be appointed by the governor and shall be recompensed either by a fee paid by the applicants who may appear before them, or they shall be salaried officers directly connected with the department in each state controlling the granting of motor licenses.

In the original report, the committee offered standards other than those concerned with visual acuity. This was done with the idea of establishing standards which in simplicity and effectiveness might correspond with those suggested for vision, the committee having in mind submitting this part of the report to the organizations within the American Medical Association more directly concerned than the Section on Ophthalmology.

In order to avoid delay, and to secure action on the standards other than those dealing with vision, your committee has sought the advice of Dr. William C. Woodward of the Bureau of Legal Medicine and Legislation of the American Medical Association, who suggested referring them for action to the Section on Preventive and Industrial Medicine and Public Health, of which Dr. Oscar Dowling is chairman. This was done, Dr. Dowling giving his personal approval to the recommendations made by your committee and referring them to his section for action. In the event such action be favorable and the revised report relating to visual standards herein presented be accepted by this section, your committee would suggest that the report in toto be submitted without further delay to the House of Delegates with the request from this section that the Association take such measures as may be within its power, to urge and aid in the establishment of these physical standards in every commonwealth, territory and possession of our country.

Respectfully submitted.

Conrad Berens.
William C. Finnoff.
Harry S. Gradle.
William Campbell Posey, Chairman.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

DIPHTHERIA IMMUNITY TEST (SCHICK TEST) (See New and Nonofficial Remedies, 1925, p. 369).

The Gilliland Laboratories, Inc., Marietta, Pa.

Schick Test (See New and Nonofficial Remedies, 1925, p. 370).—Marketed in packages containing one vial of diphtheria toxin (standardized) and one 10 Cc. vial of physiological solution of sodium chloride for dilution, the amount being sufficient for fifty tests. Two tenths (0.2) cubic centimeter of the dilution is injected intradermally, which represents 1/50 minimum lethal dose for a guinea pig of 250 gram weight. As a means of control, the Schick test control, representing diphtheria toxin of the same lot heated sufficiently to destroy the specific exotoxins, is supplied.

CORPORA LUTEA, DESICCATED-P. D. & CO.—The dried corpus luteum of cattle and swine.

Actions and Uses.—See general article, Ovary, New and Nonofficial Remedies, 1925, p. 251.

Dosage.—From 0.24 Gm. to 0.6 Gm. (4 to 10 grains) daily.

Manufactured by Parke, Davis & Co., Detroit. No U. S. patent or trademark.

Capsules Corpora Lutea, Desiccated P. D. & Co., 2 grains.
Capsules Corpora Lutea, Desiccated P. D. & Co., 5 grains.
Tablets Corpora Lutea, Desiccated P. D. & Co., 2 grains.
Tablets Corpora Lutea, Desiccated P. D. & Co., 5 grains.

The corpora lutea of swine and cattle are ground to a fine pulp and dehydrated in vacuo at a temperature not exceeding 60 C., powdered and diluted with sugar so that one grain of the dry powder represents approximately 5 grains of the fresh gland substance.

Corpora lutea, desiccated P. D. & Co. is a yellowish or brownish colored powder having a peculiar odor, partially soluble in water.

STREPTOCOCCUS VACCINE (See New and Nonofficial Remedies, 1925, p. 359).

Eli Lilly & Co., Indianapolis.

Streptococcus Vaccine.—A suspension of killed *Streptococcus pyogenes* in physiological solution of sodium chloride, preserved with 0.3 per cent of cresol. Marketed in single 5 Cc. vial packages containing 500 million killed bacteria per cubic centimeter and in single 20 Cc. vial packages containing 500 million killed bacteria per cubic centimeter.

STAPHYLOCOCCUS VACCINE (See New and Nonofficial Remedies, 1925, p. 357).

Eli Lilly & Co., Indianapolis.

Staphylococcus Vaccine.—A suspension of killed *Staphylococcus albus* and killed *Staphylococcus aureus* in equal proportions, in physiological solution of sodium chloride, preserved with 0.3 per cent of cresol. Marketed in single 5 Cc. vial packages containing 4,000 million killed bacteria per cubic centimeter and in single 20 Cc. vial packages containing 4,000 million killed bacteria per cubic centimeter.

Staphylococcus Aureus Vaccine.—A suspension of killed *Staphylococcus pyogenes aureus* in physiological solution of sodium chloride, preserved with 0.3 per cent of cresol. Marketed in single 5 Cc. vial packages containing 2,000 million killed bacteria per cubic centimeter and in single 20 Cc. vial packages containing 2,000 million killed bacteria per cubic centimeter.

ANTISTREPTOCOCCUS SERUM (See New and Nonofficial Remedies, 1925, p. 339).

Eli Lilly & Co., Indianapolis.

Antistreptococcic Serum.—A polyvalent serum obtained by immunizing horses with intravenous injections of gradually increasing doses of living streptococci. Marketed in packages of one syringe containing 10 Cc., in packages of one syringe containing 20 Cc., in packages of one vial containing 10 Cc., and in packages of one double ended vial containing 50 Cc. with apparatus for intravenous injection.

TETANUS ANTITOXIN, CONCENTRATED (See New and Nonofficial Remedies, 1925, p. 332).

Lederle Antitoxin Laboratories, New York.

Concentrated Tetanus Antitoxin (Globulin) (See New and Nonofficial Remedies, 1925, p. 332).—Also marketed in packages of one cylinder containing 10,000 units with gravity injecting outfit for intraspinal use.

PNEUMOCOCCUS VACCINE (See New and Nonofficial Remedies, 1925, p. 355).

Eli Lilly & Co., Indianapolis.

Pneumococcus Vaccine, Prophylactic.—A suspension of killed pneumococci Types I, II and III in physiological solution of sodium chloride, preserved with 0.3 per cent of cresol. Marketed in single 5 Cc. vial packages containing 5,000 million killed bacteria per cubic centimeter.

AN IMPROVED APPLICATION OF THE USE OF RENAL FLUOROSCOPY AT THE OPERATING TABLE

B. H. Hager, M.D., Madison, Wis.
Urologist, State of Wisconsin General Hospital

The application of fluoroscopy at the operating table is now conceded to be an essential prerequisite to successful surgery for renal lithiasis.

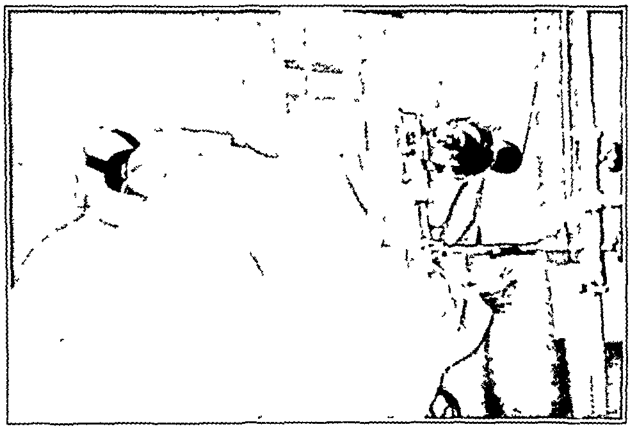

Fig. 1.—Head operating fluoroscope in use.

Braasch, in 1919, was the first to stress this principle, which has since been modified by various surgeons to meet their particular needs. By preference, some continue to use the roentgen-ray film rather than the fluoroscope. Without considering the virtues and advantages of either method, the suggestion presented here offers an advantage over fluoroscopy, which entails the presence of a radiologist. The roentgen-ray apparatus in use is a modern bedside unit with a 10 ma. Coolidge radiator tube, using a 5 ma. current.

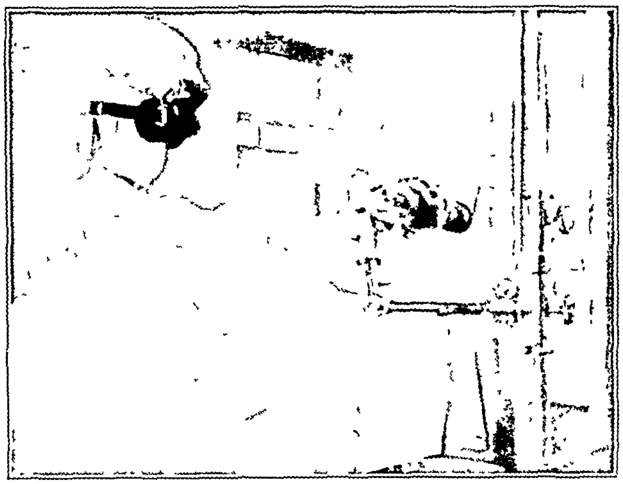

Fig 2.—The nose of the hood of the fluoroscope can be folded back, if accommodation is slow.

The accompanying illustrations show the principles of its application. As soon as renal exposure has been obtained, a nurse slips the Patterson head operating fluoroscope over the surgeon's head, a sterile cover having been slipped over the nose of the fluoroscope. The time required for accommodation is surprisingly short, much less than is usually anticipated. In persons in whom accommodation is slow, the nose of the hood can be folded back, as shown. STATISTICAL STUDIES IN CANCER

Whether cancer mortality is actually increasing, or whether the increase is only apparent and is due merely to more frequent diagnosis of the disease, are matters of constant argumentation. The influence of heredity is likewise debated. Doubtless the answers lie in statistical studies expertly pursued. The publication of the article by Schereschewsky in this issue of The Journal causes us to take account again of our knowledge in this field. In 1923, William T. Howard[1] tried to answer two questions: Is cancer actually increasing? Is it really curable? He confined himself to material found in Baltimore, where cancer mortality has been reported with fair consistency since 1813. Correcting for the increase in recorded death rates, the influence of sex, race and age, and the effect of improvement in diagnosis and statistical classification, he concluded, first, that neither the incidence nor the mortality of cancer is increasing among those exposed to risk; secondly, that, from 1880 to 1920, mortality from cancer of the breast and uterus, which can be more accurately computed than that of other organs, not only failed to increase, but, in the last half of the period, declined. This decline he attributed to medical activities; that is, to cures.

Cancer was only incidental to Raymond Pearl's[2] analysis of the situation in 1924. His intricate study, however, arrived at two conclusions that are relevant here. The first of these states that the occurrence of cancer in any individual is but slight evidence of any inherited, constitutional weakness in him. Pearl,[3] furthermore, borrowing from Dublin and Baker, gave definition to the influence of foreign stocks on cancer rates.[4] The Italians, he said, compose practically the only foreign race group whose cancer mortality is lower than that of the native born group. Of the northern European stocks, cancer incidence is high among the British and Germans, and highest among the Irish. In addition, he showed that general mortality rates, of which cancer is an element, were relatively low among Austro-Hungarians and Russians. These findings are significant in view of the fact that the volume of our immigration has decreased among northern Europeans and increased among Italians and Slavs.

Pearl and Schereschewsky in some part cover similar fields, and one confirms the other. Schereschewsky points out that the more numerous immigration of Italians and Slavs, in whom cancer incidence is lower than it was in the earlier immigrant types, had, if anything, an effect to lessen rather than to increase the cancer death rate in this country. But Howard and Schereschewsky do not agree. To be sure, Howard claimed for his work nothing more than could be inferred from statistics obtainable in Baltimore. Schereschewsky, on the other hand, included in his study the ten original registration states, and his most significant conclusion is that, with corrections made, cancer mortality is actually from 25 to 30 per cent. higher than it was twenty-one years ago.

The question no doubt arises, Have we gained anything by these studies? Each investigator is eminent in the field, and yet two of them seem to disagree on that which we wish most to know; namely, whether or not cancer is on the increase. The apparent disagreement, however, is indicative of the value of careful analysis of great, and ever greater, masses of material. The reader of any statistical results must be careful to infer from them no more than the investigator himself infers.

SLEEP

For the healthy, sleep is a hygienic necessity to well being; for the sick, it often is a requisite in the restoration of health. The suspension of consciousness, one of the features of sleep, may be brought about artificially through the action of certain drugs that intoxicate or inhibit the cerebral functions, or through the production of cerebral anemia. Anesthesia and fainting, respectively, illustrate these phenomena; consequently the question has been raised as to whether sleep in any degree partakes of such features.

Certain observations in connection with sleep have repeatedly been verified. The pulse rate decreases; the blood pressure usually falls somewhat, and there are significant changes in the distribution of blood in the body. Studies of persons in sleep seem to indicate that the minimum arterial pressure is only gradually reached; that is, rarely before the third or fourth hour. As the early period of sleep is usually that of deepest stupefaction, it becomes unlikely that the lowering of blood pressure is closely connected with the loss of consciousness. Blankenhorn and Campbell[1] of the Lakeside Hospital, Cleveland, for example, have lately made careful records on many persons showing the occurrence of the minimum systolic point (101 mm.) at the fourth hour of sleep, a slight rise before waking, and an abrupt rise after waking to a point equal to the first hour of sleep. The diastolic pressure shows a like though lesser fall. In these persons during sleep the pulse rate showed a decrease parallel in its time relations to the changes in pressure. Consequently they argue that the fall of pressure is due mainly to the fall of pulse rate, though it is probably somewhat influenced by the peripheral relaxation. Landis,[2] who has made similar measurements with comparable or even lower findings, at the University of Minnesota, has reached the conclusion, often suggested before this, that the circulatory changes are resultant from sleep rather than causative of it. He argues that if the drop in pressure were causative, then reclining, being a position favorable for loss of tone, should lead to a more pronounced pressure drop than that of the semierect position, being more conducive to sleep. However, in his experiments on man the pressure and pressure curves were practically the same in either position, while the going-to-sleep process was no more difficult in one position than in the other. This offers further evidence to Landis' belief that the sleep process is one of removal of superimposed neural control and a return to a more primitive automaticity of function.

MacWilliam[3] has presented some heretofore unappreciated aspects of the subject by emphasizing a difference between sound sleep, such as is familiarly attended with the characteristic lowering of blood pressure, and disturbed sleep and dreaming, which may be accompanied by remarkable elevations of arterial tension. In his observations, these changes were induced in the same persons by moderate exertions. In view of the rapid development of such changes in sleep, especially in dreams of motor effort and in nightmares, MacWilliam thinks it is evident that a formidable strain—harmless in the young and healthy person—may thus be thrown on the weak points of the circulatory system, whether these are cardiac with susceptibility to anginal attacks or to ventricular fibrillation and sudden death, or arterial with risk of hemorrhages, cerebral (especially in the recumbent posture), gastro-intestinal or pulmonary. If MacWilliam is correct, the conception of sleep as a period of quiescence and recuperation has thus to be qualified by the contingency of disturbed sleep with active calls on the nervous system, the heart and the blood vessels. The mechanism of the rise of pressure in disturbed sleep differs in some respects from that present in ordinary muscular exertion, since in the former the pumping action of working muscles, greatly augmenting the venous return to the heart, is absent. In other words, what is true of many factors in life seems also to apply to sleep: most sleeps are good, but some may be far better than others.

IS ACRODYNIA A NEW DISEASE?

Publicity is a potent factor for good in more than one walk of life. Even in such seemingly remote byways as clinical diagnosis and therapy, the heralding of unsuspected facts relating to disease may bring unanticipated benefits. Thus it sometimes happens that accurate description of supposedly rare human abnormalities serves to stimulate the memory of the less critical practitioner and help him recognize the real significance of pathologic entities that he may often have encountered without appreciation of their possible import. The record of a disease syndrome supposed to be novel sometimes elicits evidence that it has long been familiar to physicians who have not suspected its possible larger meaning. This seems to be true of acrodynia, a train of symptoms affecting infants and young children and described with considerable precision a few years ago by Byfield.[1] The clinical features of the disorder are manifold. There are general symptoms, such as anorexia, loss of weight and weakness. Nervous manifestations include hyperirritability, sleeplessness, paresthesia and photophobia. Dermatologic symptoms are especially conspicuous in such forms as hyperhidrosis, miliaria, desquamation, erythema and alopecia. The term acrodynia, referring to the painful extremities, describes one of the most typical symptoms of the complex, although it gives no indications of nutritional or neurologic involvements in the etiology.

That the disease here referred to is by no means uncommon is indicated by the rapid succession of case reports that followed the early exposition of the subject five years ago. Analogous, if not identical, maladies had been encountered far and wide in pediatric practice. Australia furnished a liberal number of typical cases. The writers in England also presented a quota of them. In fact, it now appears that what was regarded in 1920 as a new disease is a long recognized clinical entity classified under various names. These include the expressions "pink disease," "rawbeef feet and hands," "erythredema," and "dermatopolyneuritis," as well as the name acrodynia, which Weston[2] introduced to differentiate the disorder from pellagra, which it resembles in several respects.

Despite this multiplicity of designations, there remains a fairly definite clinical picture, which is beginning to be recognized by physicians who deal with childhood. Its etiology is not yet clear. Rodda[3] reminds us that because of its surmised resemblance to pellagra and the announcement of the "new" disease at the time when physicians were much concerned with vitamins, it is not strange that this was thought to be a deficiency disease. Rodda's own studies at Minneapolis indicate that acrodynia is usually preceded or accompanied by an upper respiratory infection. He therefore looks on it as the result of focal infection, predominantly in the tonsils and the adenoids. In his own experience, early recognition of the disorder and prompt removal of the tonsils has been followed by speedy and complete recovery in all of the youthful patients. In any event, mere dietetic and palliative treatment does not seem sufficient to avert the dangers of acrodynia. At a time when the therapeutic outlook for it has not been propitious,[4] any reasonable suggestion of rational treatment deserves a respectful hearing. Successful treatment should soon follow in the wake of the better understanding of the symptomatology. Probably, as Rodda suggests, before the advent of the roentgen ray and the Wassermann and tuberculin tests, acrodynia was at times confused with tuberculosis and syphilis, or with malnutrition of undetermined origin. The occasion for this has now passed.

PREOPERATIVE DIGITALIZATION

Tradition undoubtedly contributes much of practical benefit to medicine, for it often embodies the accumulated experience of many physicians in matters that have not been subject to strict experimental test. Thus, the undoubted virtues of fresh air and sunlight in certain conditions have a traditional history of many years, whereas the explanations of the favorable reactions which they represent are only now beginning to find expression in scientific literature. There is another type of tradition, however, represented by the blind acceptance of statements supposedly inspired by some "authority." These tend to be handed down as guides to practice, often regardless of common sense or rigorous logic, and sometimes in the face of conflict with demonstrable phenomena. These traditions may represent all shades of conviction, from fixed beliefs to wavering impressions. Because he has been told so, the convert may feel certain that night air causes malaria and may even suspect that the eating of fish is responsible for the genesis of carcinoma. It is this type of traditions that needs to be subjected to critical evaluation and clearly discussed in the light of demonstrable facts.

The dangers of "circulatory failure" and other less formidable postoperative complications are eventualities of practice that deeply concern the surgeon. Among the beliefs that are at present entertained with respect to the possibility of averting or at least minimizing such dangers is the widely claimed efficacy of digitalis in surgical patients. One may read of the advantage of preoperative digitalization in "tiding over" the periods of postoperative depression, or of averting the incidence of pneumonia after surgical intervention. A student of these varied views has remarked that most writers who recommend the frequent or routine practice of preoperative digitalization attribute its beneficial effects to the action on the blood pressure; more specifically, to its influence in maintaining pulse pressure. These are features, however, that are at present susceptible of accurate determination that ought to supplant mere conjecture with reputable facts. The problem at issue is, indeed, one of large moment in everyday clinical routine.

Notable progress in determining the facts with regard to the effects of preoperative digitalization has been made by a group of investigators[1] at the Yale University School of Medicine. The method consisted of determining the blood pressure and taking electrocardiograms at frequent intervals throughout operation, and observing any factors in the administration of the anesthetic or the surgical procedure that might be responsible for changes. Subsequently, also, the same sort of data were accumulated during the postoperative period. The observers concluded that measurements of blood pressure after operation are of no value in estimating the likelihood of complications or the rapidity of convalescence. Changes in arterial pressure in either direction seemed to be without clinical significance except when there was extreme lowering of the systolic and pulse pressures in cases of shock; in them, frequent observation of the blood pressure seemed essential. Electrocardiograms taken during operation frequently showed premature beats, paroxysmal tachycardia and disturbances of the pacemaker. These were not associated with demonstrable changes in the circulation and were regarded as without clinical significance.

A comparison of the observations on digitalized and nondigitalized patients disclosed only a few differences. There was a postoperative fall in systolic and pulse pressures in a greater proportion of the digitalized persons. Thus there was some evidence that the drug tends to cause precisely the change in blood pressure that it is usually given to avert. In any event, no evidence was secured of a beneficial effect of digitalis on postoperative complications or deaths. Many further records are essential before a final verdict can be rendered regarding the possible prophylactic value of the earlier administration of digitalis to surgical patients. The behavior of older persons, in particular, has not been thoroughly studied. But the available evidence from the Yale records gives no support to the necessity or justification for routine employment of digitalis preoperatively in patients who possess normal hearts.

Current Comment

NEW HOME FOR NEW YORK ACADEMY

October 30, the New York Academy of Medicine will hold ceremonies in connection with laying the corner stone of its new building. The academy was founded in 1843 to promote the science and art of medicine, maintain a public medical library and promote public health. Its meetings have been open to all physicians and medical students; its public medical library is the only one in New York, and the Committee on Public Health, Hospitals and Budget has been active. Thus, the academy has served well its original triplicate purpose. In 1924, as the result of conferences held to discuss ways and means of expanding the activities of the academy, the Carnegie Corporation pledged a larger building and the Rockefeller Foundation an endowment. These gifts aggregate nearly three million dollars. Such support makes possible six acquisitions: a full-time director, an executive librarian, a new library service, a bureau of clinical information, a committee on medical education, and a monthly bulletin. Of these, the bureau of clinical information publishes a daily list of operations in New York City; the Committee on Medical Education oversees local postgraduate courses and internships and gives information both to American physicians who intend studying abroad and to foreign physicians who wish to study in America. The academy has provided that none of its activities shall overlap those of the American Medical Association, the Association of American Medical Colleges, or the councils on education and on pharmacy of the American Medical Association. Here cooperation between great institutions has resulted in widening the field of usefulness to the public of the New York Academy and of the physicians of the metropolis.

"WHO'S WHO IN AMERICAN MEDICINE"

Nearly a year ago physicians were circularized by the concern "Who's Who Publications, Inc.," "M. L. Lewis, president." The letter was to the effect that a publication known as "Who's Who of American Physicians and Surgeons" was to be issued, and it was to contain brief biographical records of those physicians and surgeons of America "who had rendered marked service to their fellow men." The editor of the book was given as Winfield Scott Downs. Physicians were asked to furnish biographical data, and any suspicion as to the bona fides of the publication was allayed by the statement: "Paid material is not accepted for this publication. Hence in supplying us with your biographical material you are under no financial obligation. . . ." Undoubtedly many physicians sent in biographical data in the belief that the book was to be what was claimed, and not a few readers of THE JOURNAL wrote asking whether the proposed publication was one in which confidence might be placed. They were told that the proposed book seemed to be a routine publication venture. This implied endorsement THE JOURNAL now wishes to withdraw. The latest letter sent out by Who's Who Publications, Inc., brings out the fact that the name of the proposed book has been changed to "Who's Who in American Medicine." The letter also carries with it a subscription blank and states the condition under which a physician's biography will appear, thus: "Your biography has been selected to appear in the work, the only obligation being the acceptance of one copy of the publication, payable on delivery." From this it would appear that "Who's Who in American Medicine," instead of being a biographical list of physicians and surgeons "who have rendered marked service to their fellow men," will be a list of those physicians and surgeons who are willing to pay "$10 per copy plus cost of delivery" for the book in which their biographies will appear.

ADOLESCENT GOITER IN NEW YORK

If we accept the recent dictum that simple goiter is one of the easiest of known diseases to treat, success will depend in some measure on the prompt recognition of the condition that demands a remedy. Thyroid enlargements make their appearance at various periods of life, notably in the fetus, in adolescence, during pregnancy and at the menopause. Simple goiter has been defined as "a compensatory hyperplasia of the thyroid gland, developing during the course of certain metabolic disturbances of unknown origin, but immediately dependent on a relative or on an absolute deficiency of iodin." It is on such a condition that administration of iodin has now abundantly been demonstrated to exercise both a prophylactic and a curative effect. Surveys made in many parts of the country since the classic report of Marine and his associates about eight years ago have indicated an unanticipated incidence of thyroid enlargement among schoolchildren in certain localities often spoken of as goiter belts. For the most part these have been in the interior of the continents at considerable distances from the coastal regions. Statistics indicating, as they have, a percentage incidence of adolescent goiter ranging from 30 to 80 cannot be contemplated with complacence. It is little wonder, therefore, that both the medical profession and the lay public have become aroused to the advisability of effective measures to avert an unnecessary defect of childhood. There no longer is debate about the need of therapeutic or prophylactic attention; discussion seems at present to be confined to a consideration of the agencies best adapted to undertake the work. A rivalry between the school physician, the public health officer and the family physician has attended the efforts in some districts to promote child welfare. In respect to simple goiter, certain districts have regarded themselves as essentially immune because of their geographic location. This is true of the Atlantic seaboard. But a survey of more than 11,000 children in New York City by the Division of Educational Hygiene of the Department of Education[1] indicates an incidence of thyroid enlargement amounting to 20 per cent. among school girls of the metropolis. Such facts strongly suggest that the problem of goiter prophylaxis should not be overlooked in any place, however favorably it may appear to be situated. Large cities are centers of migration, which means environmental change for many of the population. It should also be realized that thyroid enlargement may start as a congenital defect or may begin at puberty or during pregnancy. It may not be enough to supply iodin to the adolescent. Perhaps the tendency to thyroid enlargement would be decreased if greater attention were paid to prophylaxis in expectant mothers. Information has accumulated to an extent that makes neglect inexcusable.

CARBOHYDRATE CONSERVATION IN THE BRAIN

Many years ago Huxley remarked that, in ultimate analysis, life has three legs to stand on: the heart, the lungs and the brain. In the active metabolism of the body, the lungs are concerned directly only in minor degree. Their indispensable rôle in respiration involves the functioning of a highly perfected diffusion membrane. The heart, on the other hand, is the seat of constant chemical reactions responsible for its contractile activity. What is involved thereby is indicated by a recent calculation that the maximal power of the heart is about equal to the amount of work involved in lifting the weight of the body one meter per minute.[2] Cerebral metabolism is not so conspicuous; in fact, it is only in very recent times that unmistakable quantitative evidence of chemical changes in the nervous tissue incident to activity have been accurately recorded. It has long been known that the heart is among the last of the organs to suffer depletion of its "reserves" when the body is under stress. In starvation, the cardiac muscle only slowly shows any noteworthy change in composition. The storage of carbohydrate long remains unimpaired. It is of obvious advantage that those organs which are most essential should be able to maintain their functions as long as possible when unfavorable conditions of nutrition develop. Like the heart, the brain also seems to conserve its carbohydrate reserve with great tenacity, according to experiments by Asher and Takahashi[3] at the University of Berne, Switzerland. Only under conditions that favor a state of exaggerated excitability of the central nervous system are the stored carbohydrates of the brain drawn on.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Malaria Control at Little Rock.—The malaria control division of the Little Rock Health Department cleaned 209½ miles of ditches last year and used about 16,000 gallons of oil in its malaria control work. Learning from Memphis that waste oil from oiling stations mixed with two parts of fuel oil could be used to prevent the propagation of mosquitos, 3,180 gallons were obtained from oiling stations free of charge. The malaria control area of 68 square miles, required the services of a superintendent, four inspectors, a truck driver, three ditchers and six oilers; the total cost of the work was $10,733.96. There was an increase last year in the number of cases and deaths from malaria, which the health commissioner considered probably due to frequent trips by residents into malarial districts without protection and to an increase in the number of malarial mosquitoes in the county outside the city.

CALIFORNIA

Fined for Advertising.—It is reported that Harry J. Morris, Los Angeles, was sentenced to pay a fine of $100 or serve sixty days in jail for violating the Medical Practice Act. The complaint that led to Morris' arrest was based on an advertisement in the Los Angeles Sunday *Times*. The sentence was suspended for sixty days provided Morris changes his advertising to comply with the law.

DISTRICT OF COLUMBIA

Grand Jury's Report on St. Elizabeth's Hospital.—The federal grand jury has filed in the supreme court of the District a report in which it suggests that Congress authorize the President to appoint a commission to investigate St. Elizabeth's Hospital, where 4,500 insane patients are confined. At the same time the grand jury returned an indictment charging William McIntire and Irwin R. Sweeny, attendants at the hospital, with manslaughter in connection with the death of William Green, a colored inmate, who died, July 17, 1924, due, it is said, to "a beating" he is alleged to have received. The grand jury expressed its belief that "there are many persons now confined there who are not now and never were insane, but who have been sent there for ulterior motives." The report complains further of overcrowding of patients, the "most deplorable conditions existing as a result; there are some rooms intended to accommodate twenty single beds containing more than forty beds, and there is scarcely room to walk between these beds. . . . If the overcrowded condition of the hospital is not remedied at an early date, we fear that the percentage of inmates becoming hopelessly insane will be greater than those cured, in spite of the best efforts of the superintendent and his assistants." The grand jury gave especial attention to conditions existing in Howard Hall, where the criminally insane are incarcerated and those who became insane while serving sentences in federal prisons. The report states that: "There is an open court in the center of the building about one hundred feet square called by the inmates the 'bull pen.' This is the only recreation space available and here the dangerous as well as the noisy patients mingle with those whose minds are almost normal. The sky is barely visible to the patients while they are in this court, and a glimpse of the outside world may be had by looking over the twenty-four foot wall." The grand jury's report generally approved the situation in other portions of the hospital.

The day following the presentation of the grand jury's report to the court, Secretary of Interior Hubert Work and Dr. William A. White, superintendent of the hospital, held a conference. Secretary Work vigorously denied the charge that any patients at the hospital are sane or are held there through "ulterior motives"; he stated that he was well aware that the hospital was overcrowded and that he has been making arrangements to ask Congress for appropriations to construct buildings to meet the overcrowded conditions. "I have found," said Dr. Work, "that in the artificial atmosphere of the insane asylum many inmates appear sane, but if they are permitted to be at large again they soon establish the fact that they are insane. I have no doubt that one or more of the inmates impressed members of the grand jury, but you may be sure that if any of them were sane, Dr. White would only be too glad to release them." Secretary Work further called attention to the fact that there are sixty murderers confined in Howard Hall, and that the guards who had to maintain order among them had his sympathy. "It comes to a question of whether a guard must protect himself against these criminal patients or submit to injury. It is an extra-hazardous occupation." The present vogue of sending criminals to insane asylums instead of to prisons makes the care of an institution like St. Elizabeth's arduous.

ILLINOIS

Personal.—Dr. Elbert L. Damron, Effingham, has been appointed physician for the Pennsylvania Railroad to succeed the late Dr. James H. Walker.——Mr. W. D. Wrightson failed to be reappointed as public health officer of the Quincy public health district. The board ruled that the office should be held only by a physician. A new health officer has not yet been appointed.

Baby Conferences.—About 10,000 babies were examined physically and mentally at more than seventy baby conferences held at the various fairs this fall under the auspices of the state health department. The predominating defects found were nutritional—rickets, bowlegs, knock-knees, decayed teeth, enlarged heads, flabby muscles and undersize. Each baby was rated on the basis of an examination by specialists.

Health Officers' Meeting.—Dr. Isaac D. Rawlings, state health director, has called a meeting of all health officers in the state at the National Catholic Community House, East St. Louis, 1:30 p. m., October 20. Dr. W. A. Evans, Chicago, will preside, and among others on the program are Dr. William H. Parke, New York, Surgeons C. C. Pierce and Thomas Parran, Jr., U. S. Public Health Service, and Dr. Jacob C. Krafft, Chicago, president, Illinois State Medical Society.

Infantile Paralysis.—Twenty-two cases of infantile paralysis were reported to the state department of health the first week of October, which was about double the number of each of the two preceding weeks. In July, August and September 148 cases were reported against 117 for the same months of last year, while the total number of cases up to October 5 was 213 against 186 for the same period last year. Twenty-seven cases were reported from Cook County between September 1 and October 5; thirteen from Fulton County; eight from Henry; six from Livingston. The public schools at Cornell were closed when three cases developed in that community.

Chicago

Norwegian-American Hospital Holds Graduate Clinics.—The staff of the Norwegian-American Hospital has arranged a series of graduate clinics for the winter months, covering the various phases of medical sciences, giving members of its staff and physicians in the vicinity opportunity to secure advanced information. On Monday of each week, regional anatomy is considered by Dr. O. F. Kampmeier; on Tuesday, physical diagnosis by Dr. Maurice Lewison; on Wednesday, internal medicine by Dr. S. R. Slaymaker; on Thursday, a series of urologic clinics in which Drs. B. C. Corbus, V. J. O'Conor, R. B. Herbst and H. C. Rolnik alternate; Friday evenings are to be devoted to case presentations by members of the staff, and Saturday evenings to pathologic conferences and histories under the direction of Dr. W. G. Gibbs. The program is under the direction of Dr. Harry Noskin.

Society News.—Prof. Thomas V. Smith, Ph.D., department of philosophy, University of Chicago, and associate editor of the *International Journal of Ethics*, gave the address at the annual dinner of the Chicago Medical Society, October 14. Dr. Archibald H. Logan, Rochester, Minn., and Dr. Alexander A. Goldsmith will address the society, October 21, on "Idiopathic Ulcerated Colitis, with Special Reference to Etiology and Treatment," and "Amebic Dysentery," respectively.——Drs. Herman L. Kretschmer and Edwin W. Hirsch will address the Chicago Urological Society, Hotel Sherman, October 22, on "Carcinoma of the Prostate," and "Urethral Mucosa and Glands" (lantern slide demonstration), respectively.——The Chicago Council of Medical Women will meet, October 27, 8 p. m., at the Women's City Club.——The American Academy of Ophthalmology and Otolaryngology will hold a special scientific session, October 20, 8:45 p. m., at the Sherman House. The subject will be deafness and the meeting will be open to the public.——The Northwest Branch of the Chicago Medical Society will sponsor a health show at the Logan Square Masonic Temple, 2451 Kedzie Boulevard, December 3-5, which will be endorsed by the Illinois State Medical Society. The physical examinations to be given will include children and adults. Physicians are invited to offer their services as examiners. There will be a meeting of physicians, October 23, at the temple to explain the method of awards, the instruction being given by Dr. Jacob C. Krafft, president of the Illinois State Medical Society.——Among the speakers at the recent annual meeting of the Medical Society of the Missouri Valley, St. Joseph, Mo., were Drs. Robert H. Babcock, S. R. Slaymaker and Vincent J. O'Conor, who spoke on "Functional Disorders of the Heart," "Electrocardiograph Interpretations" and "Diseases of the Kidney," respectively.

INDIANA

Personal.—Dr. Larue D. Carter, Indianapolis, was elected president of a new organization of Indiana World War physicians at an organization meeting held during the annual convention of the state medical association at Marion; Dr. Arett C. Arnett, Lafayette, was elected secretary.

Survey of Bakeries.—The state board of health recently made a survey of 150 bakeries in every part of the state. From the standpoint of sanitation only one was found excellent, seventy-four good, sixty-seven fair, six poor and two bad. The survey was intended primarily to obtain information about the raw materials used in baking, and it was found that 137 bakeries used vegetable fat in place of lard, that the vanilla in almost every bakery was an imitation or a compound; that "lemon" and "cream" as applied to pies have no specific meaning, lemon pies being flavored with lemons and acidified with citric acid, and that "cream" pies sometimes contain no dairy products whatever. Forty-eight bakeries used jam and jellies for rolls, while seventy-eight used imitations or compounds; two-thirds of the bakeries used yellow coloring material and in some instances to simulate the coloring of eggs. With but few exceptions, however, these and other raw materials found were of the highest quality.

IOWA

Personal.—Dr. Harold E. Farnsworth has resigned as city health officer of Storm Lake, and Dr. Edgar F. Smith has been appointed to that position.

City Hospitals Merged.—An ordinance was recently passed by the city council of Des Moines providing for the consolidation of all buildings, properties and medical equipment now used by the city of Des Moines for hospital purposes with the Polk County Hospital.

Dr. Lambert Resigns.—Dr. John J. Lambert, for thirty years an instructor in anatomy, histology and embryology at the University of Iowa College of Medicine, Iowa City, has resigned, effective November 1, to become associated with his brother, Dr. Charles I. Lambert, in practice in New York.

LOUISIANA

Mosquito Conference.—Mayor Behrman, New Orleans, issued formal invitations to a conference, October 14, to the mayors of thirty cities in Louisiana, Mississippi and Alabama and to the presidents of police juries in fourteen parishes in Louisiana, to make plans for a comprehensive survey to determine the best methods of attacking the problem of marsh mosquitoes. Governor Fuqua issued invitations to the conference, it is reported, to the governors of adjoining states, the secretary of agriculture, the Surgeon General, U. S. Public Health Service, and other federal sanitation experts.

Quarantine Changed for Latin American Ships.—Heretofore ships from Latin American countries have been compelled, on account of quarantine, to delay, in some cases, a considerable time at quarantine, while ships from European countries, against which there are no quarantine restrictions, have been permitted to proceed directly to the sub-boarding station at Flood Street. It has been announced that after November 1 Latin American ships entering the port of New Orleans will also be permitted to proceed directly to Flood Street, the change having been authorized by the Surgeon General, U. S. Public Health Service.

MASSACHUSETTS

Harvard Appoints Tutor for Premedical Students.—Harvard University has appointed Dr. Hallowell Davis, Boston, as official tutor and instructor in the premedical sciences, whose duty it will be to aid premedical students properly to correlate their work and advise them in planning schedules which will lay the best foundation for a medical education.

New Health Unit.—The cornerstone for the $250,000 health unit to be erected at Paris and Emmons Streets, East Boston, from the George R. White Fund was laid, October 1. This will be the second health unit provided from the White Fund, the first one being in the north end of Boston. It will be of fireproof construction, with cafeteria and locker rooms in the basement, waiting rooms connected with dental, eye, preschool and prenatal clinics on the first floor, and an auditorium with stage, motion picture booths, and offices for welfare and nurses societies on the second.

Society News.—The Worcester District Medical Society held a joint meeting with the Worcester Ninth District Society at the Country Club, Worcester, September 9. Dr. Harold M. Frost spoke on periodic health examinations.——The four western districts, Berkshire, Franklin, Hampden and Hampshire, held a joint meeting at Belchertown, September 15; eighty fellows attended the dinner. Among the speaker were Dr. James S. Stone, Boston, president of the state society, Dr. John M. Birnie, of the board of registration in medicine, Dr. Theodore S. Bacon, a trustee of the Belchertown State School, and Dr. George E. McPherson, superintendent of the school.

MICHIGAN

Typhoid Outbreak Controlled.—The outbreak of typhoid fever at Alston, amounting to about twenty cases, has been investigated by the state board of health and found to be under control. Dr. Charles H. Benning, a representative of the state board from Lansing, went to Alston to supervise antityphoid vaccinations. A feature of the outbreak was, it is reported, that no ex-soldier who had been vaccinated during the World War against typhoid contracted the disease in this epidemic.

"Minimum Program" for County Societies.—To determine the problems of county medical societies and help them develop a constructive program, the state society has arranged a series of conferences of county officers and councilors, to be held by councilor districts. Seven conferences were held in September and three have been arranged for October. A "minimum program" for county society work has been carefully prepared and unanimously approved by the council. The *Journal of the Michigan State Medical Society* says that nowhere else in the United States has this plan been contemplated.

Wayne County Medical Society.—Dr. Charles L. Mix, Chicago, professor and head of the department of medicine, Loyola University School of Medicine, addressed the medical section of the Wayne County Medical Society, October 12, on "Toxic Goiter." Dr. Herbert M. Rich will address a general meeting of the society, October 19, on "Indications for Thoracic Surgery in Pulmonary Tuberculosis;" Dr. Max Ballin will discuss the surgical side of the subject. The Public Education Committee of the society requests that all members of the Wayne County Medical Society who care to give lectures to the public this year notify the chairman, Dr. James H. Dempster, promptly.

MINNESOTA

Personal.—The board of regents of the University of Minnesota has appointed Dr. Henry E. Michelson as director of the department of dermatology and syphilology at the university.——Dr. Ernest L. Strader, Louisville, Ky., has been appointed superintendent and medical director of the Deerwood Sanatorium, Brainerd, to succeed Dr. James K. Anderson, who resigned to take charge of Sunny Rest Sanatorium at Crookston. Dr. Strader for several years has been connected with the Waverly Hills Hospital, Louisville, and the Mineral Springs Sanatorium at Cannon Falls, both tuberculosis sanatoriums.

MISSISSIPPI

Society News.—Dr. Seale Harris, Birmingham, Ala., addressed the clinical meeting of the East Mississippi Eleven Counties Medical Society at Amory, September 15, on "Diet in Peptic Ulcers," and among others, Dr. John A. Rayburn, Ecru, spoke on "Should the General Practice of Medicine Be Considered a Specialty?" The president of the state association, Dr. Giles S. Bryan, Amory, invited all ex-presidents of the state association to this meeting, and those who responded included Drs. Robert S. Curry, Jackson; Lucien C. Feemster, Tupelo; Peter W. Rowland, Oxford; Jacob S. Ullman, Natchez, and Felix J. Underwood, Jackson, the last acting as toastmaster to the banquet in the evening.

MISSOURI

Arrested for Selling "Paregoric."—Eight druggists in St. Louis were arrested, October 2, by federal narcotic agents for selling more than 2 ounces of paregoric to a patron. They were held under bonds of $1,000 each.

Student Health Service.—St. Louis University initiated this fall a student health service which will provide a clinic where each new student may apply for treatment for any ailment at any time, and provide medical service in the home of any student at any time. The service is a division of the department of internal medicine of the university under the supervision of the director of that department and under the direction of a physician directly responsible for the service.

Personal.—Dr. Wallace S. Petty, Memphis, has been appointed full-time health officer of Pemiscot County at Caruthersville.——Dr. Theodore W. Romeiser, formerly professor of neurology at St. Louis University School of Medicine, St. Louis, has been appointed to the staff of State Hospital No. 2.——Dr. Levi H. Fuson has been elected president of the staff at St. Joseph Hospital, St. Joseph.——Dr. George L. Sherman has accepted a position at the sanatorium in St. Joseph which is conducted by Dr. Charles R. Woodson.——Dr. James C. Chilton, Hannibal, has been appointed chief surgeon of the St. Louis and Hannibal Railroad.

Proposed County Health Department.—Dr. Joseph W. Mountin, Jefferson City, representing the state board of health, and others representing the county school boards, Red Cross and other organizations, appeared before the county court in St. Joseph, September 14, to advocate the establishment of a full-time county health unit in Buchanan County. Dr. Mountin said, it is reported, the unit would cost between $7,500 and $8,000, and that the state board of health would provide half that sum and that the Rockefeller Foundation and the U. S. Public Health Service would also assist. The unit as proposed would have a full-time health officer and two nurses, one maintained by the Red Cross. He said also that the county health department would carry on a program of public health education through the press, schools, moving pictures and conferences; instruction would be given in the rural districts to mothers, and health service would be established in the rural schools similar to that now in the city schools of St. Joseph, and that the sanitation of the dairies, schools and homes would be looked after.

NEW YORK

Society News.—Drs. Byron B. Bowen and Nelson G. Russell, both of Buffalo, addressed the Cattaraugus County Medical Society, Delevan, September 8, on "Present Day Problems of Diabetes" and "Treatment of Cardiac Disease," respectively.——Dr. Joseph H. Globus, adjunct neurologist to Mount Sinai Hospital, New York, addressed the Rockland County Medical Society, Letchworth Village, September 23, on "Diagnostic Features of Various Forms of Paralysis with Particular Reference to Brain Tumor and Encephalitis." The members were guests after the meeting of Dr. Charles S. Little, superintendent of Letchworth Village, at a supper which, the *New York State Journal of Medicine* says, is an annual event to which the physicians look forward with pleasure.——Dr. Henry L. Shaw, president of the Albany County Medical Society, Albany, addressed the Otsego County Medical Society at Oneonta, September 8, on "Infant Feeding"; he invited the members to an old-fashioned clam bake and dance at the Albany Country Club under the supervision of the Albany County Medical Society, September 16.

Joint Meeting on Graduate Medical Education.—A special committee on graduate medical education and the committee on public health and medical education held a joint meeting recently in Albany. There was a lengthy discussion of the principles involved in the graduate education plan of the state medical society. Formal resolutions were passed to the effect that: (1) the state committee shall work through the county and district societies and that no course shall be given except through one of them; (2) the courses in pediatrics and obstetrics that have proven successful shall be offered to the county societies as courses already avail-e; (3) the moving picture films on tuberculosis and gastric er shall be offered to the district branches for use in their ual meeting; (4) the chairman shall appoint a sub-nmittee to prepare short courses and find out from medical ools whether they would be willing to help; (5) the chair-n was authorized to arrange for such clinical lectures as Orange County Medical Society may request in con-uation of the course in operation. Dr. Charles A. Gordon, irman of the committee on public health and education, t a questionnaire to every county society to find out, among er things, what would be attractive to members in graduate ching, what the county societies are doing in graduate dical teaching, what facilities exist in the county to con-:t extension courses, and whether physicians of the county o are not members of the state society should be included.

New York City

peech Clinic Opens.—The New York University Speech nic, which operated last year, opened again, October 2, at Washington Square Building of the University. The ic is said to be the only one of its kind connected with a versity in this country.

irector of Publicity Assigned.—The board of estimate ated, October 2, the position of director of publicity and lic health education in the department of health. Dr. n Oberwager, formerly assistant to Health Commissioner naghan, has been assigned to the new position.

ore Units in Medical Center.—With the approval of the viving donors of the Sloane Hospital for Women and the nderbilt Clinic, Columbia University announced, October that these institutions will be moved to the new Medical nter at Broadway and One Hundred and Sixty-Fifth Street. e original agreements provided that should the medical ool be moved from Fifty-Ninth Street, the university uld rebuild the hospital and clinic on whatever new site s selected.

Columbia Offers Ph.D. in Public Health.—Two new posi-ns have been filled in the Institute of Public Health of lumbia University College of Physicians and Surgeons ich will permit the offering of courses leading to master science in public health and Ph.D. in public health, the ly degrees which will be offered by Columbia in this field. . Alton S. Pope has assumed the duties of assistant pro-sor in epidemiology at the institute and Dr. Frank G. dley that of assistant professor in industrial hygiene.

Personal.—Dr. Thomas D. Wood, chairman of the joint mmittee on health problems in education of the National lucation Association and the American Medical Associa-n, addressed the American Dental Association at its recent nual meeting in Louisville, Ky., on "The Cooperation of achers and Dentists in the Dental Hygiene of Children." —Dr. Anthony Bassler addressed the Academy of Medicine Columbus, Ohio, October 5, on "Medical Treatment of omach and Intestinal Conditions."——Dr. Charles P. L. athe, San Francisco, will address the genito-urinary sur-ry section of the New York Academy of Medicine, October , on "The Present Day Status of Urology in Europe."—— r. Joseph A. Blake took up his new duties, October 1, as ief of the Tarrytown Hospital.

New Activities of Academy of Medicine.—*The cornerstone* the new building of the New York Academy of Medicine ill be laid, October 30, at 4:30 o'clock. From 1843 until 24, the academy limited its activities to promoting the ience and art of medicine, to the maintenance of medical brary, and the promotion of public health. When it decided expand, the Carnegie Corporation appropriated $1,550,000 r a new academy building and the Rockefeller Foundation ,250,000 for endowment for new activities, including the pointment of a full-time director and a new executive brarian, the development of library service, the maintenance a bureau of clinical information and the publication of a ulletin. The director of the academy, who began his duties, n. 1, 1924, is a member of all committees, makes special udies of affairs suggested by the council and is general perintendent of the building. The library is the only ublic medical library in New York City. It is open daily to e public, and the staff will be increased in order to extend s activities.

Rare Communicable Diseases in New York.—In the annual port for 1924 of the Bureau of Preventable Diseases of ew York, the chief diagnostician, Dr. William L. Somerset, ives the incidence of some of the rarer communicable diseases. There were thirty-one cases of leprosy on record on Dec. 31, 1924, as against twenty-eight cases in the previous year; one patient was deported and four patients with leprosy came to the city during the year; ten patients were being treated at Riverside Hospital and the others at various clinics. There were fourteen cases of typhus fever during the year and one death, and there was no connection between these cases and recent immigrants. There were twelve cases of trichiniasis with one death; several patients became ill after an absence from the city, indicating a probability of infection elsewhere. There were twenty-eight cases of tetanus in the city, with twenty-three deaths, and three of these occurred in drug addicts. There was one case of anthrax, for which no source of contagion was discoverable; the patient recovered; there is a steadily decreasing incidence in anthrax in the city. There were only four cases of smallpox reported in Greater New York in 1924, and they were all mild. There were no cases of rabies or glanders. There were two cases of rat bite fever and both patients recovered.

NORTH CAROLINA

Revocation of License Sustained.—The superior court at Durham recently sustained the action of the state board of medical examiners in revoking the license to practice medicine of Dr. Edwin H. Bowling, Durham. Dr. Bowling was convicted in the federal court twice of violations of the Harrison Narcotic Law. The board held that these convictions were evidence of unprofessional conduct within the meaning of the statute.

Diphtheria in Isolated Village.—Responding to a call for assistance, navy medical officers went by airplane to the village of Hatteras, October 3, and found cases of diphtheria in twenty-two homes in a total population of about 600 persons. There were three cases in some homes and one child died on the above date. Hatteras is a community of fishermen and their families about 30 miles off the North Carolina coast. There is no resident physician.

OHIO

Physician Sentenced for Delaying Trial.—Dr. Louis L. Rosenberg, Toledo, was sentenced to ten days in jail and fined the costs, September 29, it is reported, on a charge of aiding in the removal of a court witness. Dr. Rosenberg, it is alleged, signed a certificate to the effect that J. C. Roberts, who was charged with liquor violation, was ill and unable to appear in court. A policeman, however, reported that Roberts was not ill and brought him into court.

Personal.—Dr. Otto P. Geier, Cincinnati, who recently returned from the International Conference on Industrial Medicine at Geneva, Switzerland, presented to Dr. Frank G. Boudreau, formerly chief of the division of communicable diseases in Ohio, a gold watch on behalf of his associates in the state department of health. Dr. Boudreau is now epidemiologist for the League of Nations.——Dr. Melville D. Ailes, Jackson Center, has been appointed health commissioner of Sidney and Shelby County to succeed Dr. Arlington Ailes, resigned.

Health Survey of Laundries.—In a general survey of health conditions in industry in Columbus, a report has been made on laundries by Dr. Nelson C. Dysart of the health department. The investigation covered fifteen laundries, which ranged in the number of employes from two to others which employed hundreds of people. The health of laundry workers generally was found to be very good, although in 1910, 1911 and 1912 the mortality rate among laundresses for pulmonary tuberculosis was reported to be 23.49; in the same period it was 7.14 for agricultural workers. All of the laundries except one used individual drinking cups and towels; the ventilation in some was only fair, but no special health hazards were found. The next investigation will be of bakeries.

A Mother at Fifty-Nine.—During 1924, in Ohio, 130,610 mothers gave birth to living children, says the state department of health. There were 1,414 pairs of twins and eleven sets of triplets; a child was born in the state every four minutes during the year; there were 67,892 males and 64,156 females. Among the triplets twelve were females and twenty-one males; there were five sets of still-born triplets, all males. The largest number of births was in August, the lowest number in November. Four of the mothers were only twelve years of age, seven were 14, eleven were 50 years, one was 51, four were 55 and one 59 years of age; 450 mothers gave birth to their twelfth child, 300 to the thirteenth, 123 to the fourteenth, 66 to the fifteenth, 25 to the sixteenth, 8 to the seventeenth, 5 to the eighteenth, two to the nineteenth and one to the twentieth child.

Society News.—At the one hundred and eighty-fourth regular meeting of the clinical and pathological section, Academy of Medicine of Cleveland, City Hospital, October 2, among others, Dr. Lawrence A. Pomeroy spoke on "Radium Implantation in Carcinoma of the Rectum," and Dr. Warner H. Tuckerman on "Mastoiditis with Thrombosis of the Jugular Vein and Lateral Sinus."——Dr. Clarence D. Selby, Columbus, president of the Ohio State Medical Association, addressed the General Practitioners Medical Society at a dinner at the Bliss Hotel, September 24, on "Social Service —A Menace or a Friend?"——The Five-County Medical Association, consisting of Fayette, Warren, Greene, Highland and Clinton counties, held a picnic at Hale Park, Wilmington, September 1, with the Clinton County Medical Society acting as host. Dr. George W. Crile, Cleveland, spoke on "Problems Relating to the Liver and Biliary Tract," and Dr. John H. J. Upham, Columbus, on "Medical Problems of Today." Dr. Crile spoke on the same subject before the Summit County Medical Society, September 8.——Dr. Charles A. Langdale delivered his presidential address before the Cincinnati Academy of Medicine, September 28, on "A Historical Discussion of Surgery in the Sixteenth Century."

PENNSYLVANIA

No Improvement in Seventeen Years.—The maternal mortality rate in Pennsylvania in 1906 was 6.1 per thousand confinements and in 1923 it was precisely the same. The state lost 1,373 mothers in 1923 as a result of childbirth, the two leading causes being septicemia (441 deaths) and the toxemias (366). A map prepared by the state department of health shows that the rate is not highest where the foreign population is centered, i. e., in the coal regions.

Personal.—Dr. John D. Donnelly, Harrisburg, a member of the administrative staff of the state department of health, has resigned to engage in private practice in Philadelphia. ——Dr. David P. McCune has been elected president of the McKeesport Academy of Medicine for the ensuing year, Dr. Joseph B. Feeley, vice-president, and Dr. John C. Kerr, secretary.——Dr. J. W. Leckie, Hazleton, has been appointed medical director of the new $450,000 West Mountain Sanatorium at Scranton which was opened recently. Dr. Leckie assumed his new duties, October 1.

Scholarships in Neuropsychiatry.—The dean of the Graduate School of Medicine of the University of Pennsylvania, Philadelphia, announced, October 3, that the Commonwealth Fund, New York, had appropriated $36,000 to support five scholarships in neuropsychiatry at that school, and that of thirty applications only three fellowships had been awarded to Dr. Bernard J. Alpers, Philadelphia; Dr. Forrest N. Anderson, U. S. Marine Hospital No. 3, Ellis Island, New York, and Dr. Paul E. Kubitscheck of Osawatomie, Kan. The fellowships are to be administered by a committee comprising the dean, George H. Meeker, Ph.D., Dr. Theodore H. Weisenburg and Dr. Earl D. Bond, all of the University of Pennsylvania, Dr. Frankwood E. Williams, and Dr. Ralph C. P. Truitt, medical director and director of the division on prevention of delinquency of the National Committee for Mental Hygiene, respectively, and Miss Mildred E. Scoville of the Commonwealth Fund.

Philadelphia

Sword Presented to University.—The sword of Dr. John Houston, surgeon of the Continental Army, and the diploma which he received from Glasgow University have been mounted on the stairway in Houston Hall at the University of Pennsylvania. Dr. Houston was a graduate of the university in 1769. The sword and diploma were presented to the university by Charles Warner Houston, Los Angeles, a great great grandson. The University of Pennsylvania furnished not only physicians but many other leaders in the army and in the Continental Congress.

Ground Breaking for Home of Medical Society.—Simple ceremonies marked the breaking of ground, October 3, preparatory to erecting the new auditorium for the Philadelphia County Medical Society, 2044 Spruce Street. The ground was turned by the president, Dr. Arthur C. Morgan, in the presence of the board of directors, the committee on home of the society, Dr. James M. Anders, historian, representatives of the Women's Auxiliary headed by Mrs. William E. Parke, state president of the auxiliary, and others. The nickel-plated spade used, the gift of the Kessler Construction Company, will be preserved in memory of the ceremony.

Physicians Organize for Sesqui-Centennial.—A number of prominent physicians of the city held a meeting in the interest of a Medical Division of the Sesqui-Centennial Exposition which will be held next year. Among those attending were Drs. Jay F. Schamberg, George M. Coates, Wilmer Krusen, director of the department of health, George A. Knowles, James T. Rugh, William D. Robinson, Benjamin A. Thomas, John D. McLean and Louis Lehrfield. Dr. Krusen accepted the captaincy of the team of physicians who will take an active part in the drive to secure $3,000,000 by the sale of participation certificates to expedite the construction of exhibit buildings. The meeting discussed plans for medical exhibits of both scientific and popular nature, and Drs. Schamberg, Coates, Rugh and Thomas, among others, signified their intention of active participation in the celebration by accepting the chairmanships of subcommittees.

SOUTH DAKOTA

Annual Clinic at Mitchell.—The fifth annual clinic for physicians of Mitchell will be November 5-6. There will be no operative work, dry clinics having been found, the chairman said, more popular and more instructive than the usual operations. Dr. Edward S. Judd, professor of surgery, Mayo Foundation, Rochester, Minn., will conduct a clinic on "Abdominal Surgery and Diagnosis"; Dr. Fred M. Smith, professor of medicine, State University of Iowa College of Medicine, Iowa City, on "Diseases of the Heart"; Dr. Arthur A. Sweeney, St. Paul, "Neurology and Psychiatry"; Dr. Hiram W. Orr, Lincoln, Neb., "Orthopedics"; Dr. Willis S. Lemon, Mayo Foundation, Rochester, Minn., "Diseases of the Chest"; Dr. Henry E. Michelson, University of Minnesota Medical School, Minneapolis, "Diseases of the Skin"; Dr. Rood Taylor, University of Minnesota Medical School, "Diseases of Children," and Dr. Harold I. Lillie, Mayo Foundation, Rochester, Minn., "Diseases of the Eye, Ear, Nose and Throat."

TENNESSEE

Hospital Survey Completed.—The mayor of Memphis called a meeting in the auditorium concert hall, October 16, to present to the public the report and recommendations of the hospital and health survey of Memphis made by Dr. Haven Emerson, New York. To secure a representative audience of persons interested in community welfare, invitations were sent to the members of all clubs and civic organizations. The underlying reason for the survey, the mayor said, was to coordinate the hospital building programs which both the city and county contemplate.

Society News.—At the fourth annual session of the Walnut Log Medical Society, Reelfoot Lake, September 29, Dr. Ira Park, Union City, was elected president; Dr. R. L. Motley, Dyersburg, secretary, reelected; Drs. Willis Moss, Clinton, Ky., and R. M. Little, Martin, vice presidents, and Dr. J. D. Brewer, Dyersburg, treasurer. A banquet followed the scientific session and plans were made for the purchase of a club house in the park.——The Southern Tuberculosis Conference will be held in Memphis, October 14-16, with Dr. Henry Boswell, Jr., of Sanatorium, Miss., presiding.

WASHINGTON

Golf Trophies.—Preceding the recent meeting of the state medical association at Seattle, Dr. George M. Horton, Seattle, donated a challenge cup to be played for annually. The winner this year was presented with a replica, and the winner of five annual tournaments will have permanent possession of the trophy. Dr. Joseph A. McKee gave a cup to the general practitioner of the state who won a 36-hole competition.

WISCONSIN

Vimedia Quack Ordered to Leave Town.—Mrs. Clara Mosher, an agent for the "Vimedia" line of nostrums, has been ordered by the Board of Health of Beaver Dam to leave the city. "Vimedia" is a combination of products similar to the "Viavi Treatment," both having been written up in "Nostrums and Quackery"; they are "female weakness cures." Mrs. Mosher ostensibly gives "health lectures" but actually sells the Vimedia products. She is said to have relieved Beaver Dam women of several thousand dollars in the sale of the "treatment." Other Wisconsin cities have been warned of her activities.

Society News.—Dr. Clarence W. Hopkins, Chicago, chief surgeon of the Chicago and Northwestern Railroad, addressed the Medical Society of Milwaukee County, October 9, on "Multiple Fractures of the Pelvis Complicated by Dislocation of the Head of the Femur," and Dr. John Powers on "Case of Central Fracture of the Acetabulum Complicated by Pregnancy"; both speakers gave lantern slide illustrations. ——Dr. Jake A. Riegel, St. Croix Falls, addressed the Barron - Polk - Washburn - Sawyer - Burnett County Medical Society at Barron, September 1, on "The Typing of Pneumonia" and, among others, Dr. William H. Hengstler, St. Paul, on "Mercurochrome in Acute Infections of the Nervous System."

New Health Program in Oshkosh Schools.—The board of education of Oshkosh unanimously adopted the recommendations of the health and recreation committee for a new health program for the schools. Local physicians will be employed to examine school children and serve as advisors at the various schools. The examinations will be made to discover organic defects so that parents may have their children treated by their family physician. A card showing the results of examinations will accompany the pupil throughout his school life. The work will be correlated under the city health department. Drs. John M. Conley, Jasper W. Lockhart, John F. Schneider, William P. Wheeler, Harry H. Meusel, John F. Stein, George A. Steele, Henry W. Kleinschmidt, William A. Wagner, Hubert J. Haubrick and Edward J. Campbell were appointed to make the examinations.

Speech Clinic.—The department of speech of the University of Wisconsin maintains throughout the academic year a clinic for the diagnosis and treatment of defects of speech. The clinic is largely diagnostic for cases outside of the student body but gives advice as to the method of treatment and where it can be obtained. A limited number of widely divergent type cases will be admitted to a six weeks' course of training in a demonstration clinic which will be conducted at the 1926 summer session; applications for this clinic should be accompanied by the history and a description of the defect. Admission to both clinics is free with the understanding that advance students in the science of speech correction will be permitted to see the cases and learn their histories. Appointments must be arranged in advance with Robert West, A.M., assistant professor of speech, Bascom Hall, University of Wisconsin, Madison.

CANADA

Hospital News.—Some old buildings in Vancouver in the block bounded by Twelfth and Thirteen Avenues and Heather and Willow Streets are being demolished in order to erect the new infectious disease wing of the General Hospital. The University of British Columbia has vacated the buildings between Tenth and Twelfth Avenues which now revert to the General Hospital.

Society News.—The October *Bulletin* of the Vancouver Medical Association, Vancouver, B. C., notes the speakers for the general meetings of the society from October 6 until the annual meeting, April 20; each alternate session will be a clinical meeting. Dr. James A. Gillespie gave his presidential address, October 6, on "The Progress and Future of Medicine"; Dr. Hibbert W. Hill will discuss "The Part Played by the Laboratory in Clinical Medicine" November 3, and Drs. Wallace A. Wilson and George Lyall Hodgins "Intravenous Therapy" December 1.

GENERAL

Investigation of Otosclerosis.—At the last meeting of the board of the Carnegie Corporation of New York, $90,000 was appropriated to the American Otological Society for an investigation of otosclerosis during the next five years.

Lectures on Birth Control.—The American Birth Control League, New York, is sending Dr. James F. Cooper, director of its clinical research department, on another lecture tour beginning October 7, at Newark, N. J., and comprising lectures almost daily until December 14 in Pennsylvania, Indiana, Illinois, Missouri, Arkansas, Texas, Louisiana, Mississippi, Alabama, Georgia, Tennessee, North and South Carolina, Virginia, West Virginia, Maryland and the District of Columbia. Dr. Cooper recently completed a tour of lectures on birth control in the Western states.

Warning: Oil Stock Operator.—A physician from Michigan writes that one E. R. Williams, who claims to represent the J. H. Fookes Company of St. Louis, has been selling Standard Oil stock in his community and that he bought some "stock." Failing to receive his certificates, he wrote to the Standard Oil Company in New York and St. Louis and to the Michigan Securities Commission and learned that there is no J. H. Fookes Company and that Williams is not authorized to sell stock in the state of Michigan. Williams has dark hair, prominent nose, large mouth, some gold filled teeth; wears glasses and is of medium height. He called on our correspondent two years ago to sell oil stock, but failed then to make "a sale."

National Board of Medical Examiners.—Connecticut now permits its examining board to grant licenses to physicians who hold the certificate of the National Board of Medical Examiners without further examination, making thirty-three states, Porto Rico and the Canal Zone which accept this certificate; 2,212 candidates have been examined since the national board's first examination, and 78 per cent. of them have passed; the number of candidates for the certificates has increased from ten, who took the first examination in Washington, D. C., October, 1916, to 978, who were examined during 1924. There will be an examination in Part III in Baltimore, October 13-16; Boston, October 26-29; Chicago, in December, and New York, in January. Candidates for these examinations should notify the board at 1600 Walnut Street, Philadelphia, at once.

Golden Rule Sunday.—The Near East Relief announces that the third annual observance of Golden Rule Sunday will be December 6. The public is requested to eat a humble meal such as homeless children under the care of Americans in the Near East eat every day in the year, and then to make a contribution to help these children. Dr. Wendell C. Phillips, New York, President-Elect of the American Medical Association, has accepted the chairmanship of the Golden Rule Sunday Cooperating Committee, which aims to promote international good will and to focus attention on the needs of the war orphans of the Near East. The appeal for funds last year was to aid 50,000 orphans; there are today about 35,000 in need, the others have either been adopted by families or placed at work in industries. Of the 35,000 who still need aid, 80 per cent. of them are less than 14 years of age. Orphanage centers under the control of Near East Relief are located in Syria, Palestine, Greece and Russian Armenia. In all of these orphanages industrial training is part of the program; nurses' training schools in Athens and Alexandropol have been organized where the older orphan girls are given training. Near East Relief has initiated medical work among these orphans and refugees; in Macedonia malaria has been reduced as a result of its campaign; the absence of typhus this year is attributed largely to precautions taken by Near East Relief workers cooperating with government agencies.

Society News.—The second annual meeting of the Eastern Society of Anesthetists will be at Philadelphia, October 26-30, at the Hotel Adelphia. There will be clinics in the mornings and discussions open to members of the profession in the afternoons, also joint sessions with the Mid-Western Association of Anesthetists, the Philadelphia Academy of Stomatology and the American Society of Regional Anesthesia. The dinner-dance will be October 28. Dr. Adolph F. Erdmann will deliver the president's address, 2:30, October 26. ——At the thirty-eighth annual convention of the Medical Society of the Missouri Valley, St. Joseph, October 1, Dr. A. D. Dunn, professor of experimental medicine, Nebraska University College of Medicine, Omaha, was elected president; Drs. H. W. Carle, St. Joseph, Mo., M. A. Tinley, Council Bluffs, Iowa, vice presidents; Dr. Charles W. Fassett, Kansas City, Mo., secretary, and Dr. O. C. Gebhart, St. Joseph, Mo., treasurer. The next annual meeting will be at Council Bluffs.——The foreign guests at the fifteenth annual meeting of the clinical congress of the American College of Surgeons, Philadelphia, October 26-30, will be Lord Dawson of Penn, London, physician in ordinary to the king; Sir William Arbuthnot Lane, London, who will deliver the John B. Murphy Oration in Surgery; Prof. Vittorio Putti, Bologna, Italy, who will speak on some phase of orthopedic surgery; Dr. Victor Pauchet, Paris, professor of clinical surgery in the School of Medicine at Amiens, who will read a paper on "Experiences in the Surgical Treatment of Gastric, Duodenal and Jejunal Ulcers"; Dr. William Blair-Bell, professor of obstetrics and gynecology, University of Liverpool, England, and Dr. Philip J. Franklin, London, eye, ear, birth to their twelfth child, 300 to the thirteenth, 123 to the fourteenth, 66 to the fifteenth, 25 to the sixteenth, 8 to the seventeenth, 5 to the eighteenth, two to the nineteenth and one to the twentieth child.

Society News.—At the one hundred and eighty-fourth regular meeting of the clinical and pathological section, Academy of Medicine of Cleveland, City Hospital, October 2, among others, Dr. Lawrence A. Pomeroy spoke on "Radium Implantation in Carcinoma of the Rectum," and Dr. Warner H. Tuckerman on "Mastoiditis with Thrombosis of the Jugular Vein and Lateral Sinus."——Dr. Clarence D. Selby, Columbus, president of the Ohio State Medical Association, addressed the General Practitioners Medical Society at a dinner at the Bliss Hotel, September 24, on "Social Service —A Menace or a Friend?"——The Five-County Medical Association, consisting of Fayette, Warren, Greene, Highland and Clinton counties, held a picnic at Hale Park, Wilmington, September 1, with the Clinton County Medical Society acting as host. Dr. George W. Crile, Cleveland, spoke on "Problems Relating to the Liver and Biliary Tract," and Dr. John H. J. Upham, Columbus, on "Medical Problems of Today." Dr. Crile spoke on the same subject before the Summit County Medical Society, September 8.——Dr. Charles A. Langdale delivered his presidential address before the Cincinnati Academy of Medicine, September 28, on "A Historical Discussion of Surgery in the Sixteenth Century."

PENNSYLVANIA

No Improvement in Seventeen Years.—The maternal mortality rate in Pennsylvania in 1906 was 6.1 per thousand confinements and in 1923 it was precisely the same. The state lost 1,373 mothers in 1923 as a result of childbirth, the two leading causes being septicemia (441 deaths) and the toxemias (366). A map prepared by the state department of health shows that the rate is not highest where the foreign population is centered, i. e., in the coal regions.

Personal.—Dr. John D. Donnelly, Harrisburg, a member of the administrative staff of the state department of health, has resigned to engage in private practice in Philadelphia.——Dr. David P. McCune has been elected president of the McKeesport Academy of Medicine for the ensuing year, Dr. Joseph B. Feeley, vice-president, and Dr. John C. Kerr, secretary.——Dr. J. W. Leckie, Hazleton, has been appointed medical director of the new $450,000 West Mountain Sanatorium at Scranton which was opened recently. Dr. Leckie assumed his new duties, October 1.

Scholarships in Neuropsychiatry.—The dean of the Graduate School of Medicine of the University of Pennsylvania, Philadelphia, announced, October 3, that the Commonwealth Fund, New York, had appropriated $36,000 to support five scholarships in neuropsychiatry at that school, and that of thirty applications only three fellowships had been awarded to Dr. Bernard J. Alpers, Philadelphia; Dr. Forrest N. Anderson, U. S. Marine Hospital No. 3, Ellis Island, New York, and Dr. Paul E. Kubitscheck of Osawatomie, Kan. The fellowships are to be administered by a committee comprising the dean, George H. Meeker, Ph.D., Dr. Theodore H. Weisenburg and Dr. Earl D. Bond, all of the University of Pennsylvania, Dr. Frankwood E. Williams, and Dr. Ralph C. P. Truitt, medical director and director of the division on prevention of delinquency of the National Committee for Mental Hygiene, respectively, and Miss Mildred E. Scoville of the Commonwealth Fund.

Philadelphia

Sword Presented to University.—The sword of Dr. John Houston, surgeon of the Continental Army, and the diploma which he received from Glasgow University have been mounted on the stairway in Houston Hall at the University of Pennsylvania. Dr. Houston was a graduate of the university in 1769. The sword and diploma were presented to the university by Charles Warner Houston, Los Angeles, a great great grandson. The University of Pennsylvania furnished not only physicians but many other leaders in the army and in the Continental Congress.

Ground Breaking for Home of Medical Society.—Simple ceremonies marked the breaking of ground, October 3, preparatory to erecting the new auditorium for the Philadelphia County Medical Society, 2044 Spruce Street. The ground was turned by the president, Dr. Arthur C. Morgan, in the presence of the board of directors, the committee on home of the society, Dr. James M. Anders, historian, representatives of the Women's Auxiliary headed by Mrs. William E. Parke, state president of the auxiliary, and others. The nickel-plated spade used, the gift of the Kessler Construction Company, will be preserved in memory of the ceremony.

Physicians Organize for Sesqui-Centennial.—A number of prominent physicians of the city held a meeting in the interest of a Medical Division of the Sesqui-Centennial Exposition which will be held next year. Among those attending were Drs. Jay F. Schamberg, George M. Coates, Wilmer Krusen, director of the department of health, George A. Knowles, James T. Rugh, William D. Robinson, Benjamin A. Thomas, John D. McLean and Louis Lehrfield. Dr. Krusen accepted the captaincy of the team of physicians who will take an active part in the drive to secure $3,000,000 by the sale of participation certificates to expedite the construction of exhibit buildings. The meeting discussed plans for medical exhibits of both scientific and popular nature, and Drs. Schamberg, Coates, Rugh and Thomas, among others, signified their intention of active participation in the celebration by accepting the chairmanships of subcommittees.

SOUTH DAKOTA

Annual Clinic at Mitchell.—The fifth annual clinic for physicians of Mitchell will be November 5-6. There will be no operative work, dry clinics having been found, the chairman said, more popular and more instructive than the usual operations. Dr. Edward S. Judd, professor of surgery, Mayo Foundation, Rochester, Minn., will conduct a clinic on "Abdominal Surgery and Diagnosis"; Dr. Fred M. Smith, professor of medicine, State University of Iowa College of Medicine, Iowa City, on "Diseases of the Heart"; Dr. Arthur A. Sweeney, St. Paul, "Neurology and Psychiatry"; Dr. Hiram W. Orr, Lincoln, Neb., "Orthopedics"; Dr. Willis S. Lemon, Mayo Foundation, Rochester, Minn., "Diseases of the Chest"; Dr. Henry E. Michelson, University of Minnesota Medical School, Minneapolis, "Diseases of the Skin"; Dr. Rood Taylor, University of Minnesota Medical School, "Diseases of Children," and Dr. Harold I. Lillie, Mayo Foundation, Rochester, Minn., "Diseases of the Eye, Ear, Nose and Throat."

TENNESSEE

Hospital Survey Completed. — The mayor of Memphis called a meeting in the auditorium concert hall, October 16, to present to the public the report and recommendations of the hospital and health survey of Memphis made by Dr. Haven Emerson, New York. To secure a representative audience of persons interested in community welfare, invitations were sent to the members of all clubs and civic organizations. The underlying reason for the survey, the mayor said, was to coordinate the hospital building programs which both the city and county contemplate.

Society News.—At the fourth annual session of the Walnut Log Medical Society, Reelfoot Lake, September 29, Dr. Ira Park, Union City, was elected president; Dr. R. L. Motley, Dyersburg, secretary, reelected; Drs. Willis Moss, Clinton, Ky., and R. M. Little, Martin, vice presidents, and Dr. J. D. Brewer, Dyersburg, treasurer. A banquet followed the scientific session and plans were made for the purchase of a club house in the park.——The Southern Tuberculosis Conference will be held in Memphis, October 14-16, with Dr. Henry Boswell, Jr., of Sanatorium, Miss., presiding.

WASHINGTON

Golf Trophies.—Preceding the recent meeting of the state medical association at Seattle, Dr. George M. Horton, Seattle, donated a challenge cup to be played for annually. The winner this year was presented with a replica, and the winner of five annual tournaments will have permanent possession of the trophy. Dr. Joseph A. McKee gave a cup to the general practitioner of the state who won a 36-hole competition.

WISCONSIN

Vimedia Quack Ordered to Leave Town.—Mrs. Clara Mosher, an agent for the "Vimedia" line of nostrums, has been ordered by the Board of Health of Beaver Dam to leave the city. "Vimedia" is a combination of products similar to the "Viavi Treatment," both having been written up in "Nostrums and Quackery"; they are "female weakness cures." Mrs. Mosher ostensibly gives "health lectures" but actually sells the Vimedia products. She is said to have relieved Beaver Dam women of several thousand dollars in the sale of the "treatment." Other Wisconsin cities have been warned of her activities.

Society News.—Dr. Clarence W. Hopkins, Chicago, chief surgeon of the Chicago and Northwestern Railroad, addressed the Medical Society of Milwaukee County, October 9, on "Multiple Fractures of the Pelvis Complicated by Dislocation of the Head of the Femur," and Dr. John Powers on "Case of Central Fracture of the Acetabulum Complicated by Pregnancy"; both speakers gave lantern slide illustrations. ——Dr. Jake A. Riegel, St. Croix Falls, addressed the Barron - Polk - Washburn - Sawyer - Burnett County Medical Society at Barron, September 1, on "The Typing of Pneumonia" and, among others, Dr. William H. Hengstler, St. Paul, on "Mercurochrome in Acute Infections of the Nervous System."

New Health Program in Oshkosh Schools.—The board of education of Oshkosh unanimously adopted the recommendations of the health and recreation committee for a new health program for the schools. Local physicians will be employed to examine school children and serve as advisors at the various schools. The examinations will be made to discover organic defects so that parents may have their children treated by their family physician. A card showing the results of examinations will accompany the pupil throughout his school life. The work will be correlated under the city health department. Drs. John M. Conley, Jasper W. Lockhart, John F. Schneider, William P. Wheeler, Harry H. Meusel, John F. Stein, George A. Steele, Henry W. Kleinschmidt, William A. Wagner, Hubert J. Haubrick and Edward J. Campbell were appointed to make the examinations.

Speech Clinic.—The department of speech of the University of Wisconsin maintains throughout the academic year a clinic for the diagnosis and treatment of defects of speech. The clinic is largely diagnostic for cases outside of the student body but gives advice as to the method of treatment and where it can be obtained. A limited number of widely divergent type cases will be admitted to a six weeks' course of training in a demonstration clinic which will be conducted at the 1926 summer session; applications for this clinic should be accompanied by the history and a description of the defect. Admission to both clinics is free with the understanding that advance students in the science of speech correction will be permitted to see the cases and learn their histories. Appointments must be arranged in advance with Robert West, A.M., assistant professor of speech, Bascom Hall, University of Wisconsin, Madison.

CANADA

Hospital News.—Some old buildings in Vancouver in the block bounded by Twelfth and Thirteen Avenues and Heather and Willow Streets are being demolished in order to erect the new infectious disease wing of the General Hospital. The University of British Columbia has vacated the buildings between Tenth and Twelfth Avenues which now revert to the General Hospital.

Society News.—The October *Bulletin* of the Vancouver Medical Association, Vancouver, B. C., notes the speakers for the general meetings of the society from October 6 until the annual meeting, April 20; each alternate session will be a clinical meeting. Dr. James A. Gillespie gave his presidential address, October 6, on "The Progress and Future of Medicine"; Dr. Hibbert W. Hill will discuss "The Part Played by the Laboratory in Clinical Medicine" November 3, and Drs. Wallace A. Wilson and George Lyall Hodgins "Intravenous Therapy" December 1.

GENERAL

Investigation of Otosclerosis.—At the last meeting of the board of the Carnegie Corporation of New York, $90,000 was appropriated to the American Otological Society for an investigation of otosclerosis during the next five years.

Lectures on Birth Control.—The American Birth Control League, New York, is sending Dr. James F. Cooper, director of its clinical research department, on another lecture tour beginning October 7, at Newark, N. J., and comprising lectures almost daily until December 14 in Pennsylvania, Indiana, Illinois, Missouri, Arkansas, Texas, Louisiana, Mississippi, Alabama, Georgia, Tennessee, North and South Carolina, Virginia, West Virginia, Maryland and the District of Columbia. Dr. Cooper recently completed a tour of lectures on birth control in the Western states.

Warning: Oil Stock Operator.—A physician from Michigan writes that one E. R. Williams, who claims to represent the J. H. Fookes Company of St. Louis, has been selling Standard Oil stock in his community and that he bought some "stock." Failing to receive his certificates, he wrote to the Standard Oil Company in New York and St. Louis and to the Michigan Securities Commission and learned that there is no J. H. Fookes Company and that Williams is not authorized to sell stock in the state of Michigan. Williams has dark hair, prominent nose, large mouth, some gold filled teeth; wears glasses and is of medium height. He called on our correspondent two years ago to sell oil stock, but failed then to make "a sale."

National Board of Medical Examiners.—Connecticut now permits its examining board to grant licenses to physicians who hold the certificate of the National Board of Medical Examiners without further examination, making thirty-three states, Porto Rico and the Canal Zone which accept this certificate; 2,212 candidates have been examined since the national board's first examination, and 78 per cent. of them have passed; the number of candidates for the certificates has increased from ten, who took the first examination in Washington, D. C., October, 1916, to 978, who were examined during 1924. There will be an examination in Part III in Baltimore, October 13-16; Boston, October 26-29; Chicago, in December, and New York, in January. Candidates for these examinations should notify the board at 1600 Walnut Street, Philadelphia, at once.

Golden Rule Sunday.—The Near East Relief announces that the third annual observance of Golden Rule Sunday will be December 6. The public is requested to eat a humble meal such as homeless children under the care of Americans in the Near East eat every day in the year, and then to make a contribution to help these children. Dr. Wendell C. Phillips, New York, President-Elect of the American Medical Association, has accepted the chairmanship of the Golden Rule Sunday Cooperating Committee, which aims to promote international good will and to focus attention on the needs of the war orphans of the Near East. The appeal for funds last year was to aid 50,000 orphans; there are today about 35,000 in need, the others have either been adopted by families or placed at work in industries. Of the 35,000 who still need aid, 80 per cent. of them are less than 14 years of age. Orphanage centers under the control of Near East Relief are located in Syria, Palestine, Greece and Russian Armenia. In all of these orphanages industrial training is part of the program: nurses' training schools in Athens and Alexandropol have been organized where the older orphan girls are given training. Near East Relief has initiated medical work among these orphans and refugees; in Macedonia malaria has been reduced as a result of its campaign; the absence of typhus this year is attributed largely to precautions taken by Near East Relief workers cooperating with government agencies.

Society News.—The second annual meeting of the Eastern Society of Anesthetists will be at Philadelphia, October 26-30, at the Hotel Adelphia. There will be clinics in the mornings and discussions open to members of the profession in the afternoons, also joint sessions with the Mid-Western Association of Anesthetists, the Philadelphia Academy of Stomatology and the American Society of Regional Anesthesia. The dinner-dance will be October 28. Dr. Adolph F. Erdmann will deliver the president's address, 2:30, October 26. ——At the thirty-eighth annual convention of the Medical Society of the Missouri Valley, St. Joseph, October 1, Dr. A. D. Dunn, professor of experimental medicine, Nebraska University College of Medicine, Omaha, was elected president; Drs. H. W. Carle, St. Joseph, Mo., M. A. Tinley, Council Bluffs, Iowa, vice presidents; Dr. Charles W. Fassett, Kansas City, Mo., secretary, and Dr. O. C. Gebhart, St. Joseph, Mo., treasurer. The next annual meeting will be at Council Bluffs.——The foreign guests at the fifteenth annual meeting of the clinical congress of the American College of Surgeons, Philadelphia, October 26-30, will be Lord Dawson of Penn, London, physician in ordinary to the king; Sir William Arbuthnot Lane, London, who will deliver the John B. Murphy Oration in Surgery; Prof. Vittorio Putti, Bologna, Italy, who will speak on some phase of orthopedic surgery; Dr. Victor Pauchet, Paris, professor of clinical surgery in the School of Medicine at Amiens, who will read a paper on "Experiences in the Surgical Treatment of Gastric, Duodenal and Jejunal Ulcers"; Dr. William Blair-Bell, professor of obstetrics and gynecology, University of Liverpool, England, and Dr. Philip J. Franklin, London, eye, ear, nose and throat surgeon to the East London Hospital. Headquarters will be at the Bellevue-Stratford Hotel. At the meeting, Monday evening, the president of the congress, Dr. Charles H. Mayo, Rochester, Minn., will induct into office his successor, Dr. Rudolph Matas, New Orleans.——At the recent annual meeting of the American Dental Association, Louisville, Ky., Dr. Sheppard W. Foster, Atlanta, was installed as president; Dr. John F. Biddle, Pittsburgh, was made president-elect; Drs. E. C. Hume, Louisville, Ky., George W. Hillias, Kansas City, Mo., and George W. Dick, Sumter, S. C., vice presidents; Dr. Otto U. King, Chicago, general secretary, reelected, and Dr. Arthur R. Melendy, Knoxville, Tenn., treasurer, reelected. The 1926 meeting will be at Philadelphia during the International Dental Congress.

FOREIGN

Richer Radium Ores.—The *Bruxelles-médical* states that the factory near Oolen producing radium from the Congo ore has turned out a total of 150 gm. of radium, 4 gm. a month on an average. Our exchange adds that there are only 310 gm. of radium known in the world to date. Certain minerals of the Congo, it is said, contain 60 per cent. of the radium-bearing uranium ore, while the United States mines had only 2 per cent.

Prize Essay on Maternal Mortality.—The permanent committee for postgraduate work of Melbourne, Australia, has awarded the prize for the best essay on maternal morbidity and mortality to Dr. E. S. Morris, of the department of public health, New South Wales, whose subject was "Salus Populi Suprema Lex." Sixteen essays were submitted. The winner will be published in the *Medical Journal of Australia.* The prize of 150 guineas was donated anonymously.

Proposed International Malaria Institute.—At the International Antimalarial Congress, Rome, October 5, the establishment of an international institute in that city for the study of malaria was endorsed by the Italian government, which promised support. The proposal was referred to the council of the congress for recommendation to the governments represented. The institute (it was proposed by the Argentine delegation) would gather information on malaria, conduct research and establish courses for physicians who desire to make a special study of malaria. The American delegation to the congress included, among others, Dr. L. W. Hackett, of the Rockefeller Foundation; Dr. Walter W. King, U. S. Public Health Service, stationed at Paris; Drs. William G. MacCallum and William S. Thayer, both of Johns Hopkins University Medical Department, Baltimore, and Dr. Richard P. Strong of Harvard University Medical School, Boston.

International Congress on Occupational Diseases and Hygiene.—The thirteen addresses at the general assembly at this meeting at Amsterdam in September have been published in a pamphlet by the *Nederlandsch Tijdschrift voor Geneeskunde.* Two addresses are in English, "Compensation to Workmen in Great Britain," by J. Glaister, and "Some Achievements of Industrial Legislation and Hygiene," by Sir Thomas Oliver; in German, F. Sauerbruch's "Tumor and Trauma," L. Teleky's "Conception and Diagnosis of Occupational Affections," R. Allers' "Fatigue," A. Wittek's "Hand Injuries," J. Akerman's "Fracture of Neck of the Femur and Compensation for This Disability," and F. Zollinger's "Tuberculosis and Trauma." The French speakers were O. Crouzon, "Occupational Nervous Maladies," B. Cuneo, "Accidents and Maladies," and A. Oller, "Functional Readaptation of the Disabled." L. Devoto, chief of the clinic at Milan exclusively devoted to occupational affections, spoke on "Pathology of the Cardiovascular Apparatus of Occupational Origin." L. Heijermans spoke in French on "Obtaining Employment for the Manually Handicapped." The address of the *Nederlandsch Tijdschrift* is Nicolaas Maesstraat 89, Amsterdam, Netherlands.

Deaths in Other Countries

Dr. **Roy Charles Merryweather,** Perth, Australia, formerly president of the Western Australian Branch of the British Medical Association and senior honorary physician at the Perth Public Hospital, July 14, of angina pectoris.——Dr. **Marie Parhon,** Jassy, noted for research in biology.——Dr. **R. Medina Jiménez,** Caracas, secretary of the Academia Nacional de Medicine, recently returned from an official mission to study malaria abroad.——Three physicians lost their lives in a recent automobile accident at the Furca, in Switzerland, Dr. **F. Grob,** Dr. **Plattner** and Dr. **Lichtenhahn-Brenner,** all of Chur or Basel.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Sept. 26, 1925.

Sir Francis Darwin

The passing of Sir Francis Darwin, botanist and biographer of his father, has a special interest for the medical profession. The third son of Charles Darwin, he was born in 1848 and was educated at Trinity College, Cambridge. After obtaining a first class in the natural sciences tripos in 1870, he completed a medical course at St. George's Hospital, London, and proceeded to the degree of M.B., but he never practiced. Like several other botanists of his generation, he studied under Sachs at the University of Wurzburg. On leaving the hospital he returned home and for eight years was his father's secretary and assistant. In 1882 he was elected a fellow of the Royal Society. From 1884 to 1888 he was university lecturer in botany at Cambridge. From 1892 to 1895 he was deputy to Professor Babington. He gave most of his time to teaching and research in plant physiology, and largely through his efforts the practical training of students in this subject was more thorough at Cambridge than at other British universities. In 1904 he collaborated with the late E. H. Acton in publishing a "Practical Physiology of Plants," a book which exercised a wide influence. His researches in plant physiology followed two main lines: 1. Researches on movement, with especial reference to the localization of irritability, which his father discovered in the root tip, and generally to the views propounded in "The Movements of Plants." The outcome was to provide considerable experimental evidence in support of Charles Darwin's views and to support the idea of the localization of sense organs, which is now generally accepted. 2. Researches on the opening and closing of stomata with reference to the physiology of transpiration. He was an ingenious and able experimenter and, like his father, preferred simple apparatus and his own contrivances. At the time of the Darwin celebrations he published "Foundations of the Origin of Species," one of many proofs of his veneration for his father's work. His "Life and Letters of Charles Darwin" is in the first rank of biographies. His chief object was to portray his father's character and he succeeded remarkably in giving a picture of the man and the student, his methods and the gradual development of his opinions. His father's love of animals, his courtesy to those who served him, his consideration for others, his modesty and his high standard of honor in his treatment of other authors, are some of the many traits inherited to a marked degree by the son.

The Boric Acid Controversy

The controversy, previously mentioned, as to whether boric acid in the quantities used for preserving food is injurious, continues. A genito-urinary surgeon wrote to the *Times* against the coming prohibition because he found boric acid in daily doses of 20 grains (1.3 gm.) well tolerated by most of his patients. He admitted, however, that in some cases there was idiosyncrasy to the drug which might cause loss of appetite, vomiting and eruptions. Mr. A. G. Foulerton, an authority on pathology and hygiene, in replying to him points out that he might have added albuminuria and even death among the possible effects of boric acid administered in medicinal doses to persons with the idiosyncrasy. Mr. Foulerton adds that boric acid is an antiseptic and not a disinfectant or germicidal drug. It merely inhibits temporarily the multiplication of bacteria; it does not destroy them. In sufficient concentration it checks and masks putrefaction. A sausage made from unsound meat, if perserved with boric acid, will remain inoffensive to the nose before the actual stage of putrefaction. But when the food is taken into the stomach the boric acid becomes diluted, the antiseptic action of the drug is lost, and the dormant bacilli will resume their activity. Mr. Foulerton also suggests that it is probable that the small doses of boric acid now taken with food are one of the causes of the prevalence of kidney disease. Kister has shown that the administration of boric acid in pharmacopeial doses (from 40 to 50 grains [2.6 to 3.25 gm.] daily) to strong, healthy men is followed after from four to ten days by albuminuria—a sign of irritative action on the kidneys. A drug which in somewhat large doses will do this, in smaller doses day by day and year by year would predispose to or cause renal disease. In the British pharmacopeia for 1885 the dose of boric acid was given as from 5 to 30 grains (0.3 to 2 gm.). Numerous cases of poisoning were recorded, and in the next edition (1898) the maximum dose was reduced to 15 grains (1 gm.). Take the case of a baby of 12 months brought up on cow's milk. The minimum amount of boric acid required to preserve milk is about 1 part in 1,000, or about 7 grains (0.5 gm.) to the pint (236 c.c.). The baby will require 2 pints (475 c.c.) of milk daily, which if boricized will mean a dose of 14 grains (1 gm.) of the acid. The medicinal daily dose, calculated from the adult dose, would be from 1¼ to 3¾ grains (0.08 to 0.24 gm.). As a matter of fact, it has been found that boricized milk may cause serious bowel disorder in infants. At present, adults may take boric acid in a large variety of foods. Sausages may contain 45 grains (3 gm.) to the pound (450 gm.); American bacon, anything up to 100 grains (6.5 gm.) to the pound. The drugging of food with substances such as boric or salicylic acid is quite unnecessary. In France, Germany, Holland, Italy, Spain and the United States, boric acid is prohibited as a food preservative. The attitude of the United States is instructive. Under the federal Food and Drugs Act of 1912, the interstate transport of boricized food is prohibited; and many states have prohibited its use within their borders. But federal law allows the exploitation of the British market: "Food products intended for export may contain added substances not permitted in food for interstate commerce, when the addition of such substances does not conflict with the laws of the country to which the food products are to be exported."

The Therapeutic Substances Act

An act has just been passed to provide for the control of the quality and authenticity of such therapeutic substances as cannot be tested adequately by direct chemical means. These consist of three groups. The first consists of biologic products (vaccines, serums, toxins, antitoxins and antigens); the second, of synthetic substances (arsphenamin and its analogues); and the third, of insulin and preparations of the pituitary gland; the manufacture of the scheduled substances is to be conducted only by persons and on premises specially licensed for the purpose, and under such conditions as may be laid down by the licensing authority. A committee has been appointed which is empowered to make regulations prescribing the standard of strength, quality and purity of any substance to which the act applies, the tests to be used, the units of standardization, the form of license and the conditions of issue. All imports must be consigned to a person licensed for the purpose and must comply with the standards in force for the home products.

Metal Artificial Limbs

A committee of inquiry appointed by the ministry of pensions shows that the all metal artificial leg is the most popular with pensioners, as it also in many cases is the most suitable from the surgical point of view. All the legs issued, with the exception of very few of the Anglesey pattern, fall into two types—the Desoutter and the Hanger-Blatchford. The prices vary from $230 for a leg for hip-joint amputation to $100 for amputation below the knee. The experts agreed that the two firms making these limbs were producing articles of outstanding design and workmanship, with a standard of fitting which gave satisfaction to both surgeon and pensioner. The committee therefore recommended that the makers employed by the ministry should be reduced to these two firms. By doing this, partial standardization will be achieved, as, while the Desoutter limb is in a category by itself, the Hanger limb is fairly representative of the other limbs now in use. There are a few exceptional cases which require special artificial limbs. The report recommends that these should continue to be provided by the ministry, on the certificate of a board of surgeons that none of the approved limbs are suitable.

The "E. R. A." Cult in New Zealand

The practice by physicians of unscientific cults, such as Abrams' method, does not receive the same indulgence in New Zealand as in England. A physician had his name removed from the medical register of New Zealand at the instance of the medical board, because he practiced the Abrams method in the diagnosis and treatment of cancer in such a manner as to show that he could not have honestly believed it was useful. The case was then taken to the court of appeal. In delivering judgment, Mr. Justice Sim said that the medical practitioners' amendment act of 1924 provided that no medical practitioner shall be deemed guilty of grave impropriety or infamous conduct in a professional respect by reason only of his having adopted and practiced any theory of medicine or surgery if in so doing he has acted honestly and in good faith. But he confirmed the judgment of the lower court. The question of the value of the Abrams system was not directly at issue in the case, he said, the only question being whether the defendant had acted honestly and in good faith. The evidence showed that although he might have believed to some extent in the Abrams system, he used it not for the purpose of benefiting the unfortunate sufferers who came to him for relief, but for the purpose of exploiting them to his own pecuniary advantage. The order fixed two years as the time after which the physician could apply for reregistration. Mr. Justice Sim thought it unfortunate that any period was fixed, for it seemed undesirable that such a practitioner by obtaining reregistration should be enabled to prey on the public.

Dozing at the Wheel

In connection with the sad death from a motor accident of a young Newcastle surgeon of much promise, the *British Medical Journal* calls attention to a possible cause of mysterious motor accidents. Mr. Hamilton Drummond was driving a car, which swerved suddenly to the left, ran into a gate, and overturned. At the inquest it was reported that he said: "I dozed over, pulled in, could not recover. Have you ever had that experience? I have done that before, but once too often." The *British Medical Journal* points out that such an accident may easily occur with a tired driver, soothed to somnolence by the rhythm of the engine and the monotonous grind of the gear. A physician on one occasion, while his new car was being driven by an employee of the manufacturers, suddenly noticed that the driver was slipping down between the steering pillar and the seat. The man was asleep. He explained the occurrence by saying that he had been driving for three days and nights. Physicians must be more liable than most people to the risk of falling asleep at the wheel, since they often have long days of tiring work. Since Mr. Drummond's death, other physicians have related their terrifying experiences of dozing while driving. More than one said that when he found the inclination to sleep overpowering he pulled to the side of the road and took a short nap.

Drastic Powers for Dealing with Tuberculous Patients

New and drastic powers for dealing with tuberculous patients have just come into force. Tuberculosis is now put in the same category as the acute infectious disease, such as scarlet fever and typhoid. The patients may be removed from their homes and taken to a special hospital and there detained. If the patient refuses to go, the local authorities may apply to a court for an order for his removal.

A Medical Insurance Scheme for the Middle Classes

While our politicians produce one scheme after another for spending the money of the overburdened taxpayer on what they are pleased to call "social reform" for the supposed benefit of those to whom, by a strange perversion of language, the term "working classes" is confined, nothing is done for the middle classes, who are morally and intellectually the superior people of the country, on whom progress in civilization has always depended. A large part of these unhappy people are now so crushed between high taxation on the one side and high prices on the other that they cannot afford to be ill, much less pay the heavy costs of an operation. Some time ago Lord Dawson of Penn, physician to the London Hospital, made the suggestion that the lamentable plight of the middle classes might be remedied by a system of insurance. But insurance experts shook their heads and declared that the cost would be too heavy for the persons requiring insurance. Incidentally, it may be remarked that they have to pay the greater part of the expense of insuring the "working classes." However, after much preliminary labor a scheme has been launched in Manchester by a company called the Family Medical Services, Ltd. The scheme is divided into two parts: first, general practitioners' fees for the whole of a family per annum; second, the cost of operations. The person who insures his family must bear a portion of the fees paid for medical attendance himself. What he receives from the underwriters will be the excess over that minimum. This seems a very wise provision, for under the national insurance system much time is wasted in dealing with persons with imaginary or trivial ailments, who would never trouble a physician if they had to pay. The ordinary rates apply to men up to 45, women up to 40 and children over 12. Children under 2 years are not accepted, and between 2 and 12 years extra premiums are charged. Also for men between 45 and 50 and women between 40 and 50 there is an extra charge of 25 per cent. No insurance is accepted on any age over 50 at entry. The whole of a family must be insured, and reductions are allowed when the number insured exceeds three. The premiums vary with the class of physician employed (i. e., with the fees). For visits not exceeding $2 the annual amount borne by the insured is $12.50, plus $3.75 for every person insured over two. A medical examination is not required on entry, but the proposal form contains detailed and exhaustive questions in order to protect the underwriters against adverse selection. The second scheme, which provides for surgical operations, is more urgent, because many middle class persons can provide for ordinary medical attendance who could not stand the heavy cost of a major operation, with the nursing and other expenses. In all cases one fifth of the cost must be borne by the insured. There are four scales according to the fees provided for. The highest scale provides $250 for a minor operation, $500 for a major operation, and $500 for nursing and other charges, with a limit of $1,000 per annum for each person. The additional premium for this is $10. Whether the scheme will prove successful remains to be seen.

BUENOS AIRES

(From Our Regular Correspondent)

Sept. 12, 1925.

Medical School Officers

Appointments have been made to the directing board of the Buenos Aires Medical School, as follows: Drs. Castex, Tamini, Speroni, Acuña and Elizalde, by the professors; Drs. Ivanissevich and Usolenghi, by the students. Drs. U. Fernández and J. Iribarne have been appointed delegates of the medical school to the superior university board.

The Alleged Serum Therapy of Syphilis

Some time ago, Drs. Lancelotti and Jáureguy announced before the National Academy of Medicine that they had inoculated human syphilis in the llama, these animals showing in a few years visceral and nervous lesions. They also described their having secured serial cultures of *Spirochaeta pallida*, which, after inoculation in the llama, yielded a serum curative of syphilis in this animal, and also offering some promise in man. They went next to Europe and presented their work to the Paris Academy of Medicine, the Pasteur Institute, Genoa, and elsewhere. All the local newspapers published repeated laudatory comments.

The alleged scientists returned to this country, for which, they claimed, their first reports were reserved. Months went by but no report was forthcoming, but advertisements of their willingness to treat patients appeared in the newspapers. After several months' watchful waiting, the Society of Biology invited both physicians to submit their evidence. The reply intimated that this would soon be presented. The Society of Dermatology repeated the invitation, but the only answer was a newspaper tirade challenging the competence of dermatologists to pass on the merits of the work. In the meantime, a number of misstatements have been found in the assertions made by both men: 1. The Paris Academy of Medicine did not endorse their work but only stated it would prove interesting to see it verified. 2. Professor Muhlens did not see and verify their cultures. 3. It is not a fact that the efficiency of the serum should have been verified in the Rawson Hospital (Dr. Seminario's service).

It may be added that Dr. Morales Villazón has stated that he had previously made attempts at immunizing the llama, but unsuccessfully.

Histologic Course

None of the foreign professors who have visited this country have made such a deep impression as Dr. P. del Rio Hortega, the histologist sent by the Post-Graduate Board of Madrid. Instead of confining himself to lectures, del Río Hortega gave actual laboratory demonstrations in normal and pathologic histology during his three months' stay. This has aroused the interest of both professors and physicians, who are now carrying out studies and experiments in accordance with the Spanish investigator's views and technic. The Academy of Medicine has appointed del Río Hortega a corresponding member.

Foreign Professors

Prof. G. Fichera of Pavia has given a series of interesting lectures on cancer.——The lectures on gastro-intestinal surgery and pathology by Prof. P. Duval, the Paris surgeon, also proved very successful.——Prof. L. Bernard, on behalf of the League of Nations, also made a brief tour here, devoting special attention to antituberculosis work.

Revision of the Curriculum

The Buenos Aires Medical Faculty will presently begin to discuss changes in the curriculum. It seems, however, that no radical reforms will be introduced. We shall go back, in all probability, to the seven-year course: three preclinical years devoted to anatomy (normal anatomy two years, and topographic anatomy one year), histology, physiology and biologic chemistry, and four clinical years with compulsory separate examinations for each special branch. The middle course examinations seem doomed, as they have proved a failure and leave only twenty-five or thirty hours for each subject. The examinations actually take up from 100 to 300 hours of the professor's time each year, while only eighty or ninety are devoted to real class work. In addition, the students flit from one examination to another, center their mind on passing them, and have no time left for serious study.

There is a tendency to limit the number of medical students, as there are more than 5,000 in Buenos Aires and 1,500 at Rosario. Some professors must teach more than 800 students. There is neither room nor facilities for such a number. The net result is that many graduates lack the necessary experience. On top of the present excess of physicians here, there are yearly over 400 graduates per 10,000 inhabitants.

New institutes will be opened especially for the chairs of clinical medicine and clinical pediatrics. A building for the dentistry school is also planned.

Sanitary Work

After a tour of inspection through the coast provinces, Dr. Aráoz Alfaro, the head of the public health department, has decided to establish a public health station at Concordia and another at Paso de los Libres. Their work will be centered on child mortality, tuberculosis and trachoma, all these conditions showing undue prevalence rates.

The government of the Santa Fe province has devoted 350,000 pesos (about $140,000) to the construction of a home for the insane, to be placed under the control of the Rosario medical school.

Rockefeller Aid

In accordance with a request from the national health department, the Rockefeller Foundation has sent a committee, including Drs. G. Strode and N. G. Davis, to organize the antimalarial work in the northern districts. The committee has visited Salta, Jujuy and Tucumán provinces and will soon have a plan ready for the work to be conducted next year.

Personal

Dr. R. Argañaraz has been appointed professor of pediatrics in the Buenos Aires medical school.

Dr. Angel Centeno, emeritus professor of pediatrics and for many years the teacher of the vast majority of Argentine pediatricians, has died.

BERLIN

(From Our Regular Correspondent)

Sept. 26, 1925.

The Session of the League of German Medical Societies

About the middle of September, the forty-fourth session of the league of German medical societies (Der deutsche Aerztevereinsbund) was held in Leipzig. The total membership of the league comprises 39,000 physicians, by far the majority of the medical profession of Germany. As an economic auxiliary of the league, the Leipziger Verband was created in 1900, to oppose the growing domination of the *Krankenkassen,* or health insurance societies. In honor of its founder, Dr. Hartmann, the name Leipziger Verband was changed, two years ago, to the Hartmann Bund. For the reason that September 13 was the twenty-fifth anniversary of the Bund, this year's session had a commemorative aspect. Therefore, the meetings of the Deutscher Aerztevereinsbund and of the Hartmann Bund were exceptionally well attended. Several of the subjects discussed have interest beyond the borders of Germany.

Dr. Vollmann, gynecologist and editor of the official organ of the Deutscher Aerztevereinsbund, discussed the increased incidence of abortion in Germany. Vollmann raised the question whether induced abortion had increased to the extent of an epidemic. There are no exact statistics on miscarriages, but from the figures of the hospitals and lying-in institutions and the reports of gynecologists, reliable conclusions may be drawn. Thirty or forty years ago, there were about nine or ten miscarriages to 100 pregnancies. Now the number is several times that—in Berlin, around forty. This increase is due to artificial interventions. In the Berlin University Women's Hospital, Bumm established that in 1916 89 per cent. of miscarriages were purposely induced According to Hirsch in Berlin, the percentage was 78 per cent, and for the 31-36 age-group even 98 per cent Such destruction of infantile life will naturally affect the birth rate. In 1901, the birth rate in Germany per thousand population was 36.9; but for Berlin it was only 27.7, and in 1923 dropped to 21.6. As against the 1,612,000 births in Germany in 1921, it is estimated, therefore, that there were 400,000 induced miscarriages. Besides the dangers for the state and nation, there are the dangers for the individual woman: acute and chronic abdominal diseases and high mortality. In 1922, abortion and miscarriage claimed a third as many victims in women of the 20-40 age-group as tuberculosis.

After discussing the historical, social, judicial and medical aspects of the problem, and after considering, favorably and unfavorably, the abolition of the law prohibiting abortion, Vollmann presented his views on the attitude of the state toward the problem. He opposes abolition of the abortion laws but would approve modifications permitting the judge to remit penalties in individual cases attended by certain distressing circumstances or impelling motives. Interruption of pregnancy which resulted from legally proved rape should not be prohibited by law. He is opposed to making a proposed induction of abortion notifiable by physicians. The sole result of such a law would be to prevent women suffering from the effects of abortion from taking advantage of skilled medical assistance. Interruption of pregnancy by a physician, carried out according to the best teachings of medicine, particularly when performed to eliminate a menace to the pregnant woman, should be permitted by law. Such interruption of pregnancy may not be undertaken for social or economic considerations, for these are not within the jurisdiction of the physician. So-called eugenic motivation (to prevent the birth of physically and mentally inferior offspring), Vollmann explained, is based on considerations that are still too unsettled to guide physicians. Aside from emergency cases, a physician should never induce abortion without consulting with at least one other physician—if possible a specialist in the branch of medicine concerned. The best method—at least in the cities—is for the local medical association to appoint physicians to serve as a board of consultation. The result of the consultation should be put in writing, with the basis for the conclusions explained. The document should be sealed and transmitted for preservation to the *Aerztekammer* (chamber of physicians), or, if there is none, to some similar medical body. The general public needs enlightenment on the biology of pregnancy and the dangers of its interruption.

Finally, viewing the recent manifestations as an epidemic, the causes should be sought that they may be eliminated. In this respect, the state has been neglectful. The state, which protects the unborn child, and compels the mother (or parents) in advance of the child's birth, to assume the care of the offspring, takes on itself certain duties. Therefore, Vollmann recommends: (1) special protection of large families (to prevent cultured nations from dying out) through remission of taxes; additional state aid for large families, for educational purposes; special privileges in the selection of dwellings; preference in land grants; remission of taxes on dwellings; favoring of officials, workmen and employees with large families; (2) endeavors to inculcate in the people a better appreciation of the value of family life; (3) municipal or communal aid for pregnant women, protection in industrial life, proper prenatal and postnatal care, cash benefits for nursing mothers; (4) protection of the unmarried mother and of children born out of wedlock, home-finding for homeless infants, with adoption made easier, and better homes for foundlings.

A number of Vollmann's recommendations were adopted by the congress. It was brought out that the spread of abortion could not be combated solely by federal and police enactments. On the other hand, the abolition of the penalties for violations of the abortion law, as proposed by the social democrats and some of the feminine advocates of women's rights, was rigorously opposed. The congress admitted, however, that in some cases a milder penalty might be indicated, and presented proposals with respect to modifications in the law.

A Proposed Federal Code Pertaining to Physicians

For some time, German physicians have sought to secure the passage of a federal code pertaining to the physicians of entire Germany, to be patterned on the federal code pertaining to attorneys. At present, aside from certain provisions in some federal laws: for example, the laws pertaining to the regulation of industries and to the organization of social insurance, the legal regulation of medical matters is a delegated power of the eighteen individual states. The result is, there is no medical body in Bavaria corresponding to the *Aerztekammern*, or "chambers of physicians," which exist in Prussia, while Prussia lacks the state insurance system for physicians, which has been created in Bavaria. The proposed code opens as follows: "The mission of the German physician is the performance of health service for the German people. The exercise of the medical profession is not an industrial undertaking performed solely as a means of making a living but must be viewed as the performance of an individual service in the care of patients and as a general service in the promotion of the welfare of the state. Undue accentuation of the commercial side of professional activities exerts a lowering effect on the morale of the profession." The main object of a code is proclaimed to be the preservation to the German people of a medical profession that is imbued with these ideals. There follows a number of provisions, such as the right of privileged communication, and some others, which are hallowed by ancient custom. An outcropping of ultramodern views, however, is the statement that the avowal of scientific, political or religious views as such, if presented in an unobjectionable way, shall not constitute a violation of the ethical code.

The health insurance societies often endeavor to convince the general public that physicians are fighting the whole system of health insurance if they but try to protect themselves against the inordinate demands of the executive committees of the *Krankenkassen*. It is therefore important that the ethical code should contain this statement: "Every physician must, to the best of his ability, promote all movements looking toward the betterment of public health, and must likewise carry out the provisions of social legislation. He must be constantly mindful in the interest of public welfare of the importance of this duty. Every physician must, within the sphere of his activity, cooperate in the prevention and in the limitation of epidemics and must not think he has done his full duty if he complies with the laws pertaining to the notification of disease." For the same reasons, conceptions regarding the rightfulness of interrupting pregnancy and bringing on sterility must correspond with the ethical code. In accordance with usual medical ethics, the proposed law provides that a physician develop his practice by his performances and not by means of advertisements, underbidding and similar methods. The physician must show proper consideration for the situation of the patient; he shall be permitted, in dealing with poor persons, to remit part or all of the fee. In evidently urgent cases he must give treatment without advance payment. In urgent cases, he must assist another physician when requested. He must not oppose the calling in of a second physician, specialist or consultant. A consultant must not refuse a consultation without having good reason. In order that the relations between physicians may be harmonious, old customs are reduced to written form; for example, the rules governing relations with patients of other physicians; the required qualifications of a specialist; on what basis recognition as a specialist can be demanded of other physicians; the relations between attending physician and consultant. Other provisions seek to dignify applications for medical posts and the drawing up of contracts. One provision deals with partnerships. While such partnerships have long been common in the United States, it is only of late that they have become more frequent in Germany. No objections are raised to partnerships as such, although it is thought they should be confined to agreements between general practitioners or between physicians practicing the same specialty. Presumably, the wording of the provision is intended to prevent too much commercialism and is based on the same considerations that actuated the provision against a physician receiving from a specialist any reward for referring patients to him. Many speakers suggested modifications in the draft. The view was also expressed that where the unwritten laws of medical ethics fail to accomplish their purpose a written code also will be ineffective. At the close, all proposals requiring further consideration were referred to a committee. The preparation of a draft for a federal code pertaining to physicians was turned over to the business committee.

BUCHAREST

(From Our Regular Correspondent)

Sept. 18, 1925.

Preventive Injections Against Infectious Diseases of Children

Dr. Alois Soriceanu, assistant at a large children's clinic in Transylvania, says that measles and diphtheria seem to be now under our control. Two thousand preventive injections of convalescents' serum failed to protect in less than 4 per cent., and even here the technic may have been at fault. The Cantacuzino Serum Works in Bucharest is now making arrangements to supply convalescents' serum regularly to institutions threatened with measles. He mentions that he injected 116 children who had been exposed to measles from two to six days before with 20 c.c. of blood from adults or older children who presumably had had measles at some time. Only twelve developed measles, and these in a mild form. He endorses Dr. Rietschel's recommendation of this as valuable prophylaxis for infants and young children in the home, whether or not the effect is to be interpreted as a specific or merely a protein reaction. But scarlet fever prophylaxis is less promising. Soriceanu on five occasions injected a total of twenty contacts with scarlet fever convalescents' serum, and none developed the disease; only three developed it among eighty-eight in an institution, and two of twenty-eight family cases in another physician's practice. The protection proved effectual in thirty-five other contacts injected and isolated at once. The whole question of scarlet fever is still unsolved, says Dr. Soriceanu. His final word is that neither active nor passive immunization has proved of any avail against whooping cough.

New Health Bill

The Roumanian government has introduced a new measure dealing with public health administration. The main features are that the existing board of public health, which is a body of lay municipal representatives, is to be replaced by a commission of twelve members nominated by the ministry of health. In the bill as it stands, four of these are to be medical men, but it is possible that this will be altered, as the medical profession in Roumania will demand that still more medical men be nominated. The most hopeful provision of the bill is the power given to create health areas under whole-time officers, but it all remains to be done by proclamation. The socialists and a section of the press clamor for some measure of free medical attendance by government physicians, but it is improbable that much in that direction will be enacted under the present bill. At the same time, the health of the people has become a political catchword in both political parties which endeavor to form the new government, so that whatever party may win, the public health will benefit. It appears almost certain that some proposal for a national medical service of a clinical nature will be instituted. In Transylvania a considerable degree of state medical attendance already exists, and many big hospitals have been government institutions for many years.

Health Bureau in Schools

To safeguard children against the spread of disease and improve the sanitation of houses in the congested quarters of Bucharest, the board of education is planning the establishment of a bureau of health. Many of the trustees favor the plan, and if enough votes can be secured in the board, the scheme will be put to a practical test as soon as the public schools are opened for the fall term. The plan is to have the schools visited by competent medical inspectors, to learn from the school children of illness in their homes. As soon as information is obtained, the affected household will be visited, and every effort made to guard against spread of the disease, and also to improve the sanitary conditions. Teachers will be requested to report cases of illness and houses which they know are not sanitary to the bureau.

Albuminuria in Relation to Diabetes

According to Dr. Hatziegan of Cluj University clinic, there are three groups of cases in which albuminuria is associated with diabetes: (1) albuminuria due to arteriosclerosis, with secondary lesions in the heart and the kidneys; (2) albuminuria of epithelial origin, due to an intercurrent disease, particularly tuberculosis, and (3) albuminuria without renal manifestation, alternating with glycosuria. In the first class of cases are frequently seen fat diabetic patients who have become albuminuriac at an age difficult to determine, on account of the insidious development of this condition and the carelessness of the patient in seeking medical advice. In these cases the albuminuria appears subsequent to the diabetes and at the same age, from 45 to 55 years, at which it appears in arteriosclerosis. The clinical features are: abundant pale urine of low specific gravity—from 1.010 to 1.020—nocturnal polyuria, and a moderate amount of albumin, with or without a slight edema. Death occurs from uremia rather than from glycosuria. In the second class of cases, tuberculosis is the most common cause of the albuminuria. Among other causes is suppuration of the bladder, which is relatively common in diabetic women, owing to the introduction of micro-organisms from without. The third class of cases are found among private rather than hospital patients, and are discovered only by accident. In these the albuminuria and glycosuria may be considered as two syndromes of similar origin; Dr. Hatziegan characterizes this association as "albuminurious diabetes" as first described by Lancereaux in France. This association is found particularly in obese and gouty patients.

The Feats of Medical Science

In an address held before the medical society at its opening session, the president, Dr. Conrad spoke on the accomplishments of medical science in relieving human suffering, as well as the numerous annoyances and drawbacks experienced by the profession in its beneficent work. He gave entertaining illustrations of some of these drawbacks: the wiles of quackery, the credulity of the public, the confusion of thrifty commercialism with ethical proprieties, the tendency to fads in the profession itself, together with the overdoing of certain methods, and the risk of falling into ruts and superficial contentment. Against all these, however, he balances the great achievements of the profession; the triumphs of surgery; the better knowledge of the origin of diseases and their treatment, and all advances tending to diminish human suffering and adding infinite possibilities of comfort and enjoyment in human existence.

According to Dr. Letanovsky, a Transylvanian surgeon, immobilization for vertebral and hip joint disease promotes the formation of bladder calculi. He has operated in twenty cases of this kind in the last five years, most of which occurred in children from 6 to 8 years old. One boy, aged 10, had to have the hip cast removed to allow suprapubic removal of a calculus. Lithiasis was suggested by incontinence day and night, frequent or interrupted micturition, hematuria, pain in the end of the penis, frequent erections, straining, and involuntary manipulation of the penis. These symptoms are rarely associated. The children's straining, in two cases, induced prolapse of the rectum, but this subsided after the removal of the bladder stone. If the child can urinate better reclining than erect, and not at all when lying prone, a calculus blocking the outlet is probable. Dr. Letanovsky urges the suprapubic incision rather than taking the chance of injuring the narrow passage by lithotrity in a child. Healing was perfect in seven of the fourteen cases in which he sutured the bladder at once.

Marriages

Francis A. Malone, Waterford, Wis., to Miss Gertrude DeKelver of Rochester, at Chippewa Falls, August 17.

Leonidas McFerrin Draper, Warrenton, N. C., to Miss Jeddie Mae Bristow of Raleigh, N. C., June 13.

Leland Francis Hyslop, Blair, Wis., to Miss Cecelia Ann McAvoy of Kingston, Ont., Canada, June 4.

Ben Spaulding Hill, Kenosha, Wis., to Miss Grace Marguerite Mattern of Mara, Pa., July 25

Evans Hugo Wangelin, St. Louis, to Miss Wilma Friend of East St. Louis, Ill., June 25.

Leonard Lee Welch, Marietta, Ga., to Miss Mary Emman Nolen of Athens, Ala., June 10.

Waldo B. Ison, East St. Louis, Ill., to Miss Henrietta Weinzel of St. Louis, July 18.

Roger B. Burrus, Hickman, Ky., to Miss Ella B. Moynor of Nashville, Tenn., June 6.

Edward F. Mielke, Appleton, Wis., to Miss Beulah Connell of Waukesha, August 18.

Etta G. Gray to Mr. Addison H. Ely, both of Los Angeles, recently.

Deaths

John Blasdel Shapleigh ⊕ St. Louis; St. Louis Medical College, 1881; member of the American Otological Society; lecturer, diseases of the ear, 1886-1890, St. Louis Medical College; dean, 1901-1902, professor of otology, 1899-1912, clinical professor, 1912-1922 and since 1922 emeritus professor, Washington University School of Medicine; on the staffs of the Barnes, St. Louis Children's, and Barnard Free Skin and Cancer hospitals and St. Luke's Hospital, where he died, September 15, following an operation, aged 67.

Otis D. Stickney ⊕ Atlantic City, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1902; member of the American Academy of Ophthalmology and Oto-Laryngology and the Philadelphia Laryngological Society; on the staff of the Atlantic City Hospital; aged 47; died, September 27, of injuries received in an automobile accident.

Harry Humfreville ⊕ Waterville, Kan.; Kentucky School of Medicine, Louisville, 1875; formerly president of the Marshall County Medical Society; for forty years surgeon to the Missouri Pacific Railroad; at one time county health officer; aged 71; died, September 9, at the Grandview Sanitarium, Kansas City, following a long illness.

Hunter Samuel Woodbery ⊕ De Land, Fla.; University of Virginia Department of Medicine, Charlottesville, 1911; president and formerly secretary of the Volusia County Medical Society; served in the M. C., U. S. Army, during the World War; at one time on the staff of De Land Memorial Hospital; aged 38; died in September, at Capitola.

James A. McLaughlin ⊕ Minneapolis; McGill University Faculty of Medicine, Montreal, Que., Canada, 1894; served in the M. C., U. S. Army, with the rank of captain, during the World War; formerly on the staff of the City Hospital; aged 55; died, September 16, following a long illness.

Charles Harper Walworth, Oakland, Calif.; California Eclectic Medical College, Los Angeles, 1897; College of Physicians and Surgeons of San Francisco, 1901; on the staff of the Berkeley (Calif.) General Hospital; aged 60; was killed, July 19, in an automobile accident.

Patrick Walter H. McKeown, Toronto, Ont., Canada; Trinity Medical College, Toronto, 1889; M.R.C.S., England, 1890; associate professor of clinical surgery, University of Toronto Faculty of Medicine; on the staff of St. Michael's Hospital; aged 59; died, September 4.

Emmett Starke Ballard, St. Joseph, Mo.; Bellevue Hospital Medical College, New York, 1898; member of the Missouri State Medical Association; formerly city physician and member of the board of education; aged 50; died, September 24, following a long illness.

Westerfield B. England, Mudlick, Ky.; University of Tennessee College of Medicine, Memphis, 1900; Hospital College of Medicine, Medical Department Central University of Kentucky, Louisville, 1906; aged 50; died, September 18, at Waco, Texas

George Melbourn Depew, Summer Shade, Ky.; Vanderbilt University Medical Department, Nashville, Tenn., 1893; for several years postmaster of Summer Shade; aged 64; died, September 20, of heart disease.

George B. Hoopingarner, Elkhart, Ind.; Medical College of Indiana, Indianapolis, 1882; Jefferson Medical College of Philadelphia, 1888; member of the Indiana State Medical Association; aged 66; died, September 19, of heart disease.

Spencer Marcus Rice ⊕ Terre Haute, Ind.; State University of Iowa College of Medicine, Iowa City, 1879; formerly on the staff of St. Anthony's Hospital; aged 70; died, September 20, at Rochester, Minn., of cerebral hemorrhage.

Charles Thomas Ballantyne, Ottawa, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1900; on the staff of the Ottawa Civic Hospital; aged 49; died suddenly, June 10, of angina pectoris.

Julius I. Metzger, New York; Medical Department of Columbia College, New York, 1882; member of the Medical Society of the State of New York; aged 66; died, September 29.

Henry Boteler Gross, Jefferson, Md.; University of Maryland School of Medicine, Baltimore, 1871; for many years member of the board of education; aged 76; died, September 14.

Humphrey Swain, Goshen, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1866; Civil War veteran; aged 82; died, September 11, of cerebral hemorrhage.

Elmer E. Kelso, Mooresville, Ind.; Medical College of Indiana, Indianapolis, 1891; aged 62; died, September 22, at the Methodist Hospital, Indianapolis, following a long illness.

Carlisle Lamar Nottingham ⊕ Cape Charles, Va.; Maryland Medical College, Baltimore, 1905; aged 41; died, September 18, at Saranac Lake, N. Y., of pulmonary tuberculosis.

Augustus R. Schaefer, Alexandria, Ind.; Eclectic Medical Institute, Cincinnati, 1881; aged 64; died, September 20, at a hospital in Logansport, following a long illness.

Henry S. Garfield, Pendleton, Ore.; Hahnemann Medical College of the Pacific, San Francisco, 1890; county coroner; aged 65; died, September 17, of heart disease.

William Leland Hughlett ⊕ Cocoa, Fla.; Medical College of Virginia, Richmond, 1884; formerly a member of the state legislature; aged 63; died, September 18.

Sheppard Emmitt Brinson, Stillmore, Ga.; University of Georgia Medical Department, Augusta, 1885; aged 74; died, September 20, following a long illness.

Peter Stuart, Guelph, Ont., Canada; Detroit (Mich.) Medical College, 1881; L.F.P.S., Glasgow, 1883; aged 65; died, August 25, following a long illness.

John Burritt Mann, Peterboro, Ont., Canada; University of Toronto Faculty of Medicine, 1910; aged 40; died, September 25, of burns received in a fire.

Murdock Alexander Macaulay, Halifax, Nova Scotia, Canada; Dalhousie University Faculty of Medicine, Halifax, 1904; aged 61; died, August 9.

Thomas Walter Wiley, McKinney, Texas; Atlanta Medical College, 1859; Confederate veteran; aged 86; died, September 14, following a long illness.

Barnum L. Cleveland, Flint, Mich.; Cleveland University of Medicine and Surgery, 1870; aged 80; died, September 19, of carcinoma of the stomach.

James Walter Reynolds, Brundidge, Ala.; University of Alabama School of Medicine, Tuscaloosa, 1885; died, September 21, of heart disease.

John Kelly Crawford ⊕ Cooperstown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1868; aged 83; died in September.

Harvey Edward Scott, Battle Wharf, Ala.; Vanderbilt University Medical Department, Nashville, Tenn., 1880; aged 70; died September 2.

Samuel John Kirk, Macleod, Alta., Canada; University of Manitoba Faculty of Medicine, Winnipeg, 1898; aged 55; died, August 7.

William Jay McClintock, Waycross, Ga.; Washington University Medical School, St. Louis, 1902; aged 67; died, September 18.

James Robert Laing, Hamilton, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1917; aged 33; died recently.

James Ross Collie, River John, Nova Scotia, Canada; Medical School of Harvard University, Boston, 1869; aged 84; died, July 11.

Peter F. Gates ⊕ Chicago; Harvey Medical College, Chicago, 1903; aged 64; died, August 1, of acute dilatation of the heart.

Henry W. Parchen, Phillips, Neb.; Northwestern Medical College, St. Joseph, Mo., 1882; died, August 27, following a long illness.

Thomas L. Keys, Rockwell, Texas; University of Louisville (Ky.) School of Medicine, 1885; aged 69; died in September.

William Wallace Wharton Courtney, Detroit; Detroit College of Medicine and Surgery, 1891; aged 64; died, September 19.

Patrick H. Swaim, Ridge Farm, Ill. (licensed, Illinois, 1882); aged 75; died, September 23, of cerebral hemorrhage.

Robert Emmett Bird, Rockport, Mo.; Medical College of Ohio, Cincinnati, 1879; aged 70; died, September 13.

The Propaganda for Reform

In This Department Appear Reports of The Journal's Bureau of Investigation, of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

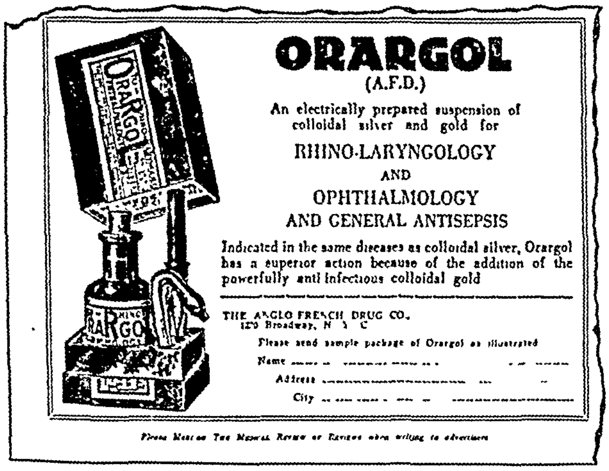
ORARGOL NOT ACCEPTABLE FOR N. N. R.

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report.

W. A. Puckner, Secretary.

Orargol (The Anglo-French Drug Co., New York) is stated to be a colloidal suspension of silver and gold prepared electrically from an alloy composed of gold, 10 per cent. and silver 90 per cent. Orargol is marketed in two forms: Orargol Injectable, containing colloidal gold and silver 0.05 per cent. and Orargol Noninjectable for external use and oral administration, containing colloidal gold and silver, 0 1 per cent.



ORARGOL
(A.F.D.)
An electrically prepared suspension of colloidal silver and gold for
RHINO-LARYNGOLOGY
AND
OPHTHALMOLOGY
AND GENERAL ANTISEPSIS

Indicated in the same diseases as colloidal silver, Orargol has a superior action because of the addition of the powerfully anti infectious colloidal gold

THE ANGLO FRENCH DRUG CO.

Please Mention The Medical Review of Reviews when writing to advertisers

In advertising it is claimed that silver and gold are "the most active antiseptics of all the colloidal metals used against infectious conditions." It is claimed:

> "Indicated in the same diseases as colloidal silver, Orargol has a superior action because of the addition of the powerfully anti-infectious colloidal gold, also for the reason that the particles of both metals are in a state of much finer sub-division—and therefore, more active—than can be obtained by chemical means."

No evidence of any kind was submitted to show that this mixture has the antiseptic action attributed to it, or to substantiate the claim that the metals in Orargol are more finely divided than can be obtained by chemical means. If the antiseptic activity of Orargol is due to the ionized metals, as is probable, a finer grain of the colloids would not necessarily insure high activity. In fact, the preparation has a slightly astringent action on the nasal mucosa, indicating the presence of ionized metal although the information furnished by the Anglo-French Drug Company implies that the metals are present only in colloidal form. These claims must be considered unwarranted until they are supported by acceptable evidence.

No evidence was presented to the Council for the claim that Orargol *has a superior action over colloidal silver preparations* because of the presence of the gold. Until this claim is established, the combination of silver and gold in one mixture must be considered irrational.

On the basis of the available evidence, the Council declared Orargol inadmissible to New and Nonofficial Remedies because the claims made for it are unwarranted and because it is an unscientific mixture.

RAYMINOL NOT ACCEPTABLE FOR N. N. R.

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report.

W. A. Puckner, Secretary.

Rayminol (Doyle), according to its proprietors, the Phairmount Laboratories of Hackensack, N. J., provides a marked advance in "catalytic therapy." The preparation is offered to physicians "as a worthy member of your armamentarium" and "with the profoundest respect of your trust—and a deep admiration of your ethical selectiveness."

According to the label, Rayminol is "an inimitable composition founded upon exhaustive research," and is stated to be "a scientific union of liquid petrolatum, aromatized rhubarb and phenolphthalein (0.03 gm. to each 4.0) pancreatized." The term "pancreatized" is explained in the firm's advertising by the claim that Rayminol contains "an extract of the entire pancreas Gland containing all of the constituents of the gland; exhibiting great potency in respect to the Enzymes, Trypsin, Amylopsin, Lipase . . ." The amount of this extract or its potency is not declared. From these statements it appears that Rayminol is claimed to be a preparation containing liquid petrolatum, phenolphthalein, a preparation of rhubarb, and a pancreatic preparation, all in undeclared amounts except the phenolphthalein, which appears to be present in the proportion of 0.03 gm. per 4 c.c. (one-half grain per fluidrachm).

According to the label on the trade package, Rayminol is "a perfect internal cleanser—lubricant and intestinal digestive, especially indicated in the various stages of constipation." The following also appears on the label:

> "Rayminol (Doyle) is peculiarly suitable for intestinal therapy—it will control fermentative and putrefactive changes in the intestines and thus prevent the constitutional absorption of the products of such changes—assists in intestinal digestion generally and subdues catarrhal and inflammatory processes affecting the liver and bile tract.
>
> "Rayminol is one of the most efficient and complete products for constipation, or rather autointoxication which constipation causes—affecting the brain, nervous and muscular systems with fermented poisons and wastes—the underlying cause of many a case of 'blues'—nervous depression—despondency—'too tired to think' feeling—biliousness—headache, *some forms of indigestion, stomach trouble and gastritis.*"

It is not true that Rayminol is a perfect intestinal digestive or internal cleanser (whatever that may be taken to mean), or that it is especially indicated in all cases of constipation. The broad claim that Rayminol subdues catarrhal and inflammatory processes affecting the liver and bile tract is obviously false The routine administration of a pancreatin preparation in the treatment of constipation is irrational. The mixture is especially objectionable in that the dose (one to four teaspoonfuls twice a day) contains from one to four grains of phenolphthalein: four grains of phenolphthalein a day is excessive for routine use.

Rayminol is unacceptable for New and Nonofficial Remedies because it is a complex, irrational mixture of indefinite composition, which is marketed under a nondescriptive name with unwarranted therapeutic claims and in a manner that fosters the ill-advised use of purgatives by the public.

Accidents at Coal Mines.—One hundred and ninety-five lives were lost in coal mine accidents in August in the United States, according to the Department of Commerce. The fatality rate was 3.63 per million tons of coal mined, a reduction of 11 per cent. from the fatality rate of August of last year. Ten men were killed at Wilkes-Barre, August 3, in an explosion. There were forty-six fatalities at anthracite mines in Pennsylvania and 149 in bituminous mines throughout the country. For the first eight months of this year there were 1,461 fatalities at mines, and for the same period last year 1,661. The fatality rate for this period is 3 83 per million tons of coal mined while for last year in the same period it was 4.57 per million tons of coal mined, a reduction of 16 per cent. Ten major disasters with a total loss of 198 lives occurred during the first eight months of 1925 and seven major disasters with a total loss of 408 lives in the corresponding period last year.

MEDICAL SHORT STORY WRITERS

To the Editor:—I am interested in compiling a collection of short stories written by physicians. As many of these stories are published under assumed names, or the medical degree of the author is omitted, it is difficult to locate them. I am therefore writing to ask that if you or your readers know of any short stories published by medical men you will kindly communicate the fact to me.

Harold Hays, M.D.,

New York.

CANCER HEREDITY

To the Editor:—I am quoting from the remarks of Dr. F. C. Wood of New York (The Journal, October 3, p. 1050) on the subject of cancer heredity: "Of course, the animal experimentation done by Maud Slye in Chicago and by Bullock and Curtis in my laboratory have definitely proved that in animals a susceptibility to cancer is transmissible. Of that there is no question. The breeding experiments, however, are so complicated and take so long that if they were applied to human beings *it would mean that for the last 5,000 years both parents of these unfortunate human beings would have had to have cancer.* That is a concentration of breeding which cannot occur in the human race. So the facts of the high incidence of cancer in these experimental studies cannot be applied in full value to human beings."

Exactly what Dr. Wood meant in the portion that I have italicized is not clear, but there is no meaning which these words could possibly have which in any way represents the scientific facts.

The 100 per cent. cancer strains that have been produced in any laboratory have been produced from a double cancerous parentage somewhere in the line. But this does not mean that there must have been a series of double parentage for any length of time corresponding to anything like 5,000 years of human heredity, or even for more than one generation. Double cancerous parentage for one generation only will produce 100 per cent. cancerous offspring, exactly as double albino parentage for one generation only will produce 100 per cent. albino offspring.

The long series of many generations of 100 per cent. cancer have been charted, not because countless generations were necessary to produce them, but to demonstrate that they actually *were* 100 per cent. cancer strains and continued so for as many generations as we continued a double cancerous parentage. It is not alone these strains of double cancerous parentage which prove the inheritability of cancer, but still more potent in this proof is the behavior of cancer in hybridization.

Only two generations of exact facts are necessary to demonstrate what this behavior is where the cross is between a cancerous individual and a noncancerous individual who is not a cancer carrier. Three generations of exact facts—not of double cancerous parentage—are necessary to determine how cancer behaves in heredity when a hybrid carrier is mated with a cancerous individual, or with a noncancerous individual that is not a cancer carrier. This is true in mice, in man or in any other animal, or in any plant.

This demonstration of the behavior of the cancer tendency in hybridization has been shown in many charts published from this laboratory for the last fifteen years.

It is the behavior of any character in hybridization which indisputably proves its inheritability, since only heredity could explain the segregating out and the transmission as such of a character unchanged, when the two parents are unlike in any given character, as they must be in a true hybridization.

The difficulty in studying human heredity is not that we cannot have double cancerous parentage, or any other type of double parentage for 5,000 years, but that we cannot get the exact facts for even one generation. It is because of this lack of exact facts and because we cannot experiment on human beings in this and many other lines that we must get our exact facts from animal experimentation.

That we are justified in applying these facts, where they are basic biologic facts, is one of the best assets derived from the discovery of the fact of evolution.

Maud Slye, Chicago.

Chicago.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

MERCUROCHROME — SUCTION APPARATUS — DIET AND SIZE OF CHILD

To the Editor:—1. Is there danger of poisoning from mercurochrome-220 in the hands of the laity? 2. Is there any other suction apparatus than Sorensen's on the market for use in tonsil work, etc.? 3. A woman went to a city hospital to be confined and was delivered of a 6½ pound baby. It was said that the baby was small because of prescribed diet. Can the baby's weight be effectually controlled; if so, by what diet list? Does the underfed, small baby have as good a start in life as the larger, well nourished one? We have read of undernourished mothers in famine stricken countries and during war times bearing rickety and marantic children. What is the difference?

J. G. Walker, M.D., Attica, Kan.

Answer.—1. Since mercurochrome-220 soluble contains from 23 to 25 per cent. of mercury, there would seem to be a possible danger that it might decompose to liberate this drug in its ionic (potent, poisonous) form. However, sufficient evidence has been published by Drs. Young, Scott and Hill (*J. Urol.* **12**:237 [Sept.] 1924) to show that mercurochrome causes little or no gastro-intestinal disturbance until it has been taken in large doses for a week or more. They definitely conclude that it is nonpoisonous, after having administered it to patients in doses of from 0.9 to 1.2 gm. daily for as many as ten days at a time. In New and Nonofficial Remedies, 1925, page 232, it is stated that no systemic effects have been observed following the local application of mercurochrome in man. These considerations, together with the additional fact that the preparation sold to the public is marketed only in small packages of solution, would seem to make the use of mercurochrome by the laity no more dangerous than that of tincture of iodin.

2. Suction and pressure machines are offered by the following firms:

V. Mueller & Co., 408 South Honore Street, Chicago: the "Beck-Mueller."
Jaeckh Manufacturing Company, 422 East Sixth Street, Cincinnati: the Robertson anesthesia, suction and pressure cabinet.
Toledo Technical Appliance Company, 2226 Ashland Avenue, Toledo, Ohio: the McKesson apparatus.
J. Sklar Manufacturing Company, 133 Floyd Street, Brooklyn: the Sklar E. N. T. specialist's outfit.
The Mim Company, 632 Woodward Building, Washington, D. C., makes suction tubes for tonsillectomy.

3. The matter of influencing the weight and size of the new-born child by means of diet seems to be of continual interest, since queries regarding it have already been answered in the columns of The Journal on two occasions, Nov. 16, 1916, and March 2, 1918. For many centuries the notion has been prevalent that if the women eat gluttonously during pregnancy and do not take much exercise, the children will be overdeveloped and difficult deliveries will result. As laziness in the latter weeks is likely to postpone the birth, overgrowth of the child from prolonged pregnancy would add to the dystocia. While no one has made any scientific study of this particular aspect of the matter, experience seems to point to the truth of the notion. On the other

hand, experience and scientific research seem to prove conclusively that it is impossible to influence the size and weight of the new-born child by any special diet during pregnancy excepting by actual starvation. In this event, abortion and premature labor are more common.

In 1889, Prochownik recommended a diet poor in carbohydrates and water for the last six weeks of pregnancy with the single purpose of reducing the fat of the child and stated that in three cases he had facilitated labor in contracted pelves. A few American authors believe in this diet, but the majority do not. English and French writers mostly are silent on the subject. Among the Germans, Bumm, Jaschke and Pankov and Stoeckel give no value to it and quote the great experiment of the hunger blockade during the war in confirmation.

Bumm says that during the hunger blockade the children were born "fat and rosy." Stoeckel says that on the war ration the women bore larger children than usual. Eisenreich said that, during the war, babies were not smaller than before and quotes Bruening to substantiate his statement.

One American author, after describing Prochownik's diet, says that his "few experiences with it have been absolutely negative, and, indeed, daily observation in other cases, for example, tuberculosis, carcinoma, hyperemesis gravidarum and diabetes, show that the nutrition of the mother has little effect on the growth of the child, which is in fact a parasite." Dr. Hugo Ehrenfest of St. Louis gave this subject a critical study in 1919, and those interested should consult his paper. He comes to the conclusion expressed above and shows that the child is a parasite on the mother, forcing precedence for its own nourishment at her expense. He quotes the studies of numerous physiologists which do not justify the assumption that there is increased nutrition of the fetus in the presence of increased nutritive material. The size of the child is dependent on the length of the pregnancy, endocrinal balance, heredity and constitution and, it might be added, the state of health of the endometrium and placenta. Ehrenfest concludes that the preponderance of the evidence, both clinical and laboratory, proves that restriction of diet short of absolute starvation has no effect on the size of the child An obstetrician in a clinic in which two attending men are committed to dieting and sweating pregnant women states that babies delivered by him live alongside the others. After many years of observation, he declares that there is no appreciable difference in size, in weight or in vitality.

ASTHMOLYSIN

To the Editor:—I am enclosing a card relative to asthmolysin. May I suggest that you put a notice in The Journal about this German proprietary?

O. B. Fossum, M.D., San Luis Obispo, Calif.

Answer.—From German pharmaceutic and chemical journals it appears that asthmolysin has been on the market for at least ten years.

According to the advertising, asthmolysin is "a combination of the suprarenal and pituitary hormones in distinct proportions" which is prepared by a "special method."

In the series of articles on glandular therapy, published under the auspices of the Council on Pharmacy and Chemistry, Dr. Joseph L. Miller states (The Journal, Nov. 29, 1924, p. 1769) that the use of pituitary in bronchial asthma is contraindicated.

FREEZING OF BIOLOGIC PREPARATIONS

To the Editor:—Kindly advise whether freezing is detrimental to what good there may be in: (1) mixed cold vaccines; (2) canine rabies vaccine (single dose); (3) pollen extract; (4) typhoid serum for immunization; (5) insulin, and (6) the serums and vaccines in general. Some druggists are using iceless refrigeration, which brings the temperature down low enough to freeze these articles solid. Please omit my name.

M.D., Cleveland.

Answer.—There is no indication in the present knowledge that freezing interferes seriously, if at all, with the antigenic or immunizing properties of vaccines and pollen extracts, provided the temperature is fairly constant and the products in question are not frozen and thawed repeatedly over a considerable period. In the case of diphtheria toxin-antitoxin, the question of the effects of freezing has not been settled finally; but, as it is possible that freezing may reduce the antitoxic power of diphtheria antitoxin, it is now recommended that mixtures containing the minimum practical amount of toxin (one-tenth L+ dose in an injection) be used (E. R. Kelly, G. W. McCoy and others, The Journal, Feb. 16, 1924, p. 567). It follows that possibly freezing may reduce antitoxic or anti-infectious properties of other serums, and probably it is most desirable to keep serums and vaccines at a temperature a little above freezing.

We do not know of any "typhoid serum" for immunization. Vaccines composed of killed bacilli are used for that purpose.

There does not seem to be anything known concerning the effects of freezing on insulin.

YELLOW FEVER COMMISSION — TYPHOID FEVER IN AMERICAN EXPEDITIONARY FORCES

To the Editor.—Kindly tell me: 1. Who were the four members of the commission of the United States Army Medical Department who went to Cuba in 1900 to prove the mosquito theory of the transmission of yellow fever, and which one of these men deliberately allowed himself to be bitten by an infected mosquito and died of the disease? 2. How many members of the A. E. F. contracted typhoid fever, and how many died of the disease?

Mrs. Walter M. Briggs, Bowling Green, Ky.

Answer.—1. The U. S. Army medical officers composing the Yellow Fever Commission were Drs. Walter Reed, James Carroll, Jesse W. Lazear and Aristides Agramonte. Dr. Carroll contracted yellow fever experimentally and recovered; Dr. Lazear was bitten by an infected mosquito experimentally and did not contract the disease; later, however, he was bitten accidentally by a mosquito in the yellow fever ward and contracted the disease and died.

2. In the Surgeon General's report for the year 1919, page 47, is this statement: "With the same admission rates for typhoid fever in 1917-1918 as in 1861-1862, there would have been 226,001 cases and 62,694 deaths; as it was, there were 1,083 cases and 158 deaths."

ARGYRIA — TWILIGHT SLEEP

To the Editor.—1. Is there any possible danger of argyria from repeated application of argyrol to mucous surfaces? I have in mind especially a patient who is frequently troubled by an irritating conjunctivitis after exposure to dust. The usual washes have no effect, but instillation of a drop of 25 per cent. argyrol in each eye gives immediate relief. This is done sometimes twice a week, sometimes once in two and four weeks. 2. Are there any figures available as to the present general use of twilight sleep in obstetrics, and its effect, if any, on maternal and neonatal mortality?

M.D., Ill.

Answer.—1. Following is a list of references to cases of argyria following the use of silver preparations:

Myers, C. N.: Argyria and Its Relation to Silver Therapy: I. Argyria—Historical; II. Retention and Elimination of Silver with Special Reference to Silver Salvarsan and Silver Therapy, *Am. J. Syph.* **7:** 125 (Jan.) 1923.
Olson, G. M.: Argyria Localis Due to Organic Silver Preparations, The Journal, July 14, 1917, p. 87.
Crispin, A. M.: Argyrism Following Use of Collargol, The Journal, May 2, 1914, p. 1394.
Jones, M.: Argyrosis: Two Cases Accompanying Chronic Sinusitis, *Laryngoscope* **35:** 38 (Jan.) 1925.
Davis, T. D.: Argyria, with Report of Two Cases Due to Argyrol, *Virginia M. Month.* **51:** 154 (June) 1924.
Firth, D., and Harrison, G. A.: Case of Argyria, *Brit. J. Dermat.* **36:** 105 (March) 1924.

2. A complete discussion on the present status of scopolamin-morphin amnesia in obstetrics may be found in De Lee's "Principles and Practice of Obstetrics," page 314.

MERCURIC CHLORID — TOBACCO

To the Editor:—1. Is the use of a 1: 4,000 mercuric chlorid solution as a vaginal douche in leukorrhea, at intervals of several days, injurious? 2. If an asthma patient shows a negative skin reaction to tobacco, is it safe to conclude that its use, even if excessive, is without effect on his disease?

M.D.

Answer.—1. A 1 : 4,000 mercuric chlorid solution may, if repeated sufficiently often, cause mercurial poisoning from cumulative absorption of the mercury precipitated on the mucous membrane. For this reason, a less toxic antiseptic is preferable.

2. No. Excessive use of tobacco acts as an irritant to the respiratory mucous membrane, and may aggravate the bronchitis accompanying asthma.

THE AUDITION DEVICE FOR HEARING

To the Editor:—Will you kindly inform me of the status of the devices made by the Audition Corporation, Wilson Building, Hoboken, N. J.?

C. C. Bunch, Iowa City.

Answer.—The Audition device is made apparently for the purpose of producing noises and vibrations. The otologists who have given it a thorough trial believe that it may be of some value to persons who hear better in a noisy place, but even in such instances the response is beneficial only for a few hours.

We do not know of any "typhoid serum" for immunization. Vaccines composed of killed bacilli are used for that purpose.

There does not seem to be anything known concerning the effects of freezing on insulin.

YELLOW FEVER COMMISSION — TYPHOID FEVER IN AMERICAN EXPEDITIONARY FORCES

To the Editor:—Kindly tell me: 1. Who were the four members of the commission of the United States Army Medical Department who went to Cuba in 1900 to prove the mosquito theory of the transmission of yellow fever, and which one of these men deliberately allowed himself to be bitten by an infected mosquito and died of the disease? 2. How many members of the A. E. F. contracted typhoid fever, and how many died of the disease?

Mrs. Walter M. Briggs, Bowling Green, Ky.

Answer.—1. The U. S. Army medical officers composing the Yellow Fever Commission were Drs. Walter Reed, James Carroll, Jesse W. Lazear and Aristides Agramonte. Dr. Carroll contracted yellow fever experimentally and recovered; Dr. Lazear was bitten by an infected mosquito experimentally and did not contract the disease; later, however, he was bitten accidentally by a mosquito in the yellow fever ward and contracted the disease and died.

2. In the Surgeon General's report for the year 1919, page 47, is this statement: "With the same admission rates for typhoid fever in 1917-1918 as in 1861-1862, there would have been 226,001 cases and 62,694 deaths; as it was, there were 1,083 cases and 158 deaths."

ARGYRIA — TWILIGHT SLEEP

To the Editor:—1. Is there any possible danger of argyria from repeated application of argyrol to mucous surfaces? I have in mind especially a patient who is frequently troubled by an irritating conjunctivitis after exposure to dust. The usual washes have no effect, but instillation of a drop of 25 per cent. argyrol in each eye gives immediate relief. This is done sometimes twice a week, sometimes once in two and four weeks. 2. Are there any figures available as to the present general use of twilight sleep in obstetrics, and its effect, if any, on maternal and neonatal mortality?

M.D., Ill.

Answer.—1. Following is a list of references to cases of argyria following the use of silver preparations:

Myers, C. N.: Argyria and Its Relation to Silver Therapy: I. Argyria—Historical; II. Retention and Elimination of Silver with Special Reference to Silver Salvarsan and Silver Therapy, *Am. J. Syph.* **7:** 125 (Jan.) 1923.
Olson, G. M.: Argyria Localis Due to Organic Silver Preparations, The Journal, July 14, 1917, p. 87.
Crispin, A. M.: Argyrism Following Use of Collargol, The Journal, May 2, 1914, p. 1394.
Jones, M.: Argyrosis: Two Cases Accompanying Chronic Sinusitis, *Larynooscope* **35:** 38 (Jan.) 1925.
Davis, T. D.: Argyria, with Report of Two Cases Due to Argyrol, *Virginia M. Month.* **51:** 154 (June) 1924.
Firth, D., and Harrison, G. A.: Case of Argyria, *Brit. J. Dermat.* **36:** 105 (March) 1924.

2. A complete discussion on the present status of scopolamin-morphin amnesia in obstetrics may be found in De Lee's "Principles and Practice of Obstetrics," page 314.

MERCURIC CHLORID — TOBACCO

To the Editor:—1. Is the use of a 1: 4,000 mercuric chlorid solution as a vaginal douche in leukorrhea, at intervals of several days, injurious? 2. If an asthma patient shows a negative skin reaction to tobacco, is it safe to conclude that its use, even if excessive, is without effect on his disease?

M.D.

Answer.—1. A 1: 4,000 mercuric chlorid solution may, if repeated sufficiently often, cause mercurial poisoning from cumulative absorption of the mercury precipitated on the mucous membrane. For this reason, a less toxic antiseptic is preferable.

2. No. Excessive use of tobacco acts as an irritant to the respiratory mucous membrane, and may aggravate the bronchitis accompanying asthma.

THE AUDITION DEVICE FOR HEARING

To the Editor:—Will you kindly inform me of the status of the devices made by the Audition Corporation, Wilson Building, Hoboken, N. J.?

C. C. Bunch, Iowa City.

Answer.—The Audition device is made apparently for the purpose of producing noises and vibrations. The otologists who have given it a thorough trial believe that it may be of some value to persons who hear better in a noisy place, but even in such instances the response is beneficial only for a few hours.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

American Board of Otolaryngology: Chicago, Oct. 19. Sec., Dr. H. W. Loeb, 1402 South Grand Blvd., St. Louis, Mo.

Arkansas: Little Rock, Nov. 10-11. Sec., Reg. Bd., Dr. J. W. Walker, Fayetteville.

California: Sacramento, Oct. 19-22. Sec., Dr. Charles B. Pinkham, 906 Forum Bldg., Sacramento.

Connecticut: New Haven, Nov. 10. Sec., Reg. Bd., Dr. Robert L. Rowley, 79 Elm St., Hartford; Sec., Homeo. Bd., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

Maine: Portland, Nov. 10-11. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

Massachusetts: Boston, Nov. 10-12. Sec., Dr. Frank M. Vaughan, 144 State House, Boston.

Missouri: Kansas City, Oct. 27-30. Sec., Dr. James Stewart, Jefferson City.

Nevada: Carson City, Nov. 2. Sec., Dr. Simeon L. Lee, Carson City.

New Jersey: Trenton, Oct. 20-21. Sec., Dr. Alex. Macalister, Trenton Trust Bldg., Trenton.

Philippine Islands: Manila, Nov. 10. Sec., Dr. Jose V. Gloria, 686 Rizal Ave., Manila.

South Carolina: Columbia, Nov. 10. Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

Connecticut July Reciprocity Report

Dr. Robert L. Rowley, secretary of the Connecticut Medical Examining Board, reports that 25 candidates were licensed by reciprocity and one candidate was licensed by endorsement of credentials at the special meeting held at Hartford, July 31, 1925. The following colleges were represented:

LICENSED BY RECIPROCITY

College	Year Grad.	Reciprocity with
College of Physicians and Surgeons, Chicago	(1910)	Wisconsin
Rush Medical College	(1924)	Illinois
Johns Hopkins University	(1921)	Maryland
Boston University	(1923)	Mass.
Harvard University..(1910, 2) Maine, Massachusetts,	(1923)	Michigan

Colorado July Examination

Dr. David A. Strickler, secretary, Colorado Board of Medical Examiners reports the written examination held at Denver, July 7, 1925. The examination covered 8 subjects and included 80 questions. An average of 75 per cent. was required to pass. Of the 41 candidates who took the physicians' and surgeons' examination, 34, including one osteopath, passed, and 7, including one osteopath and one undergraduate, failed. Fourteen candidates were licensed by reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
University of Colorado School of Medicine	(1925)	76.8, 79.5, 81.2, 82.1, 82.3, 83.2, 83.5, 84.1, 84.6, 85.7, 85.9, 86.3, 86.7, 87, 87.6, 87.6, 87.8, 88.4, 88.6, 88.6, 88.7, 88.8, 89.3, 90.2, 91, 92.9

Book Notices

The Action and Uses in Medicine of Digitalis and Its Allies. By Arthur R. Cushny, M.A., M.D., LL.D., Professor of Pharmacology in the University of Edinburgh. Cloth. Price, $6. Pp. 303, with 76 illustrations. New York: Longmans, Green & Co., 1925.

Cushny has performed a difficult task with consummate skill and, as he says, no essential paper has escaped attention. This may surprise some whose prolific writings have contributed nothing of permanent value to the subject. The pharmacologist will find an excellent analysis of previous work, and the clinician will find that the conclusions reached are set forth in simple terms. On the other hand, few will find all parts of the monograph of equal interest and some will prefer to omit the first four chapters, which deal mainly with the general characters of members of the digitalis group and their action on the frog's heart. These details are complex, and Cushny says (p. 70) that the subject lacks practical therapeutic interest. A brief summary of the action of digitalis on the frog's heart is given on page 77. The chapter that deals with the action on the mammalian heart is less difficult, fortunately, for an understanding of this is essential for the therapeutic use of digitalis bodies. Few details of this monograph can receive consideration in a short review such as this, but attention may be directed to Cushny's explanation (p. 131) of the periodic variation in the systolic and diastolic excursions of the auricles and ventricles so often observed in the laboratory. The sixth chapter deals with blood pressure and vascular action, and it is to be hoped that Cushny has given a quietus to a pernicious view that long dominated many minds with reference to the supposed danger of using digitalis in the presence of high blood pressure. Another fallacy, as widely held at one time, but of less importance, concerns the use of digitalis in aortic insufficiency. Cushny says that while digitalis is often useless in this condition, because such patients do not present themselves for treatment until the damage has become irreparable, the slight increase in the regurgitation due to the slowing induced is of minor importance and may be more than compensated for by the increased output of the heart due to digitalis. The seventh and eighth chapters treat of the action on various organs and tissues and the problems of absorption, distribution, elimination and cumulation. The latter subject is no longer the bugbear of digitalis therapy that it was for many years, and Cushny calls attention to the fact that this persistence and summation of action are an advantage whereby a smooth therapeutic stage may be attained without danger to the patient.

The author states (p. 209) that in no department of medicine have the results following animal experimentation been more quickly applied in the explanation of therapeutic experiences and theories, and that after the physiologic doctrines of Gaskell began to be applied to clinical problems, and the study of function had obtained greater recognition, more progress was made in the therapeutic use of digitalis in fifteen years than had been made in the previous century. Attention is called to the undue emphasis that has been placed on the slowing of the heart, though slowing is often absent when digitalis proves beneficial. The author explains clearly why the high initial dosage that Eggleston has recommended is entirely safe when one observes the precautions that are especially enjoined. The author adopts a cautious attitude toward the routine use of digitalis in pneumonia and holds that the evidence does not justify its use until cardiac symptoms indicate it. He does not recommend it in hemorrhage and shock. He does not discuss the use of digitalis preliminary to surgical operations, probably because no satisfactory evidence is afforded by work that has been done in that field. The value of the assay of these drugs as well as its limitation is recognized by Cushny, and his argument in its favor will convince any skeptic, unless he is one of those that will find it equally incomprehensible whether the amount of active principle is expressed in milligrams or in frog units.

It is especially desirable that those who believe the difficulties and disappointments that follow the use of official preparations of digitalis may be avoided by the use of one of the proprietary substitutes advertised with extravagant claims should read what Cushny has to say. Concerning such articles, he says (p. 263), "Much less are the preparations available for therapeutic purposes to be regarded as pure substances or as incorporating the whole virtues of digitalis. This would be of less moment if these so-called digitalines, digitoxins, gitalins and digalens were reliable in strength; unfortunately, it has not yet been proved possible even for the same manufacturer working by the same method to put a uniform product on the market. And the more elaborate the method, the more do different samples of the final product seem to vary in strength. The 'pure principles' of digitalis on the market are to be regarded with distrust and to be prescribed with care." With especial reference to the fear of cumulation, he says, "Any digitalis preparation that is not cumulative and that does not produce nausea is inert and so weak that it is valueless. Cumulation and emesis are the essence of the digitalis action and can no more be eliminated than the spots on the leopard's skin—none of them is superior to a carefully standardized pharmacopeial preparation and all are sold at extravagant prices. In some instances the strength has been found to vary widely and this is a source of danger."

The bibliography of about 600 references is valuable because of the quality of the papers rather than because of the number of the references. There is an index showing the pages of the book where each paper is considered. Cushny states that most of those who have compared the chief drugs of the group revert to digitalis, but it is astonishing that he does not take a more positive stand with reference to the preeminence of digitalis among the drugs of this group for oral administration. Cushny has performed a great service to pharmacologists and practitioners, and the book deserves careful reading.

A Preliminary Report on the Treatment of Interstitial Keratitis. By R. Lindsay Rea, M.D., F.R.C.S., Ophthalmic Surgeon to West End Hospital for Nervous Diseases. Cloth. Price, 2 shillings 6 pence net. Pp. 32, with illustrations. London: H. K. Lewis & Co., 1925.

This report is based on ninety-one cases seen by the author in the various English hospitals over a period of several years. In this series he found the proportion of males to females to be in relation of 1 to 1.87 and the ages to vary from 5 to 49 years. Sixty-four of the seventy-two cases that were examined serologically gave a positive Wassermann reaction and five of the eight negative cases gave a positive colloidal gold test. The etiology was not discussed in the remainder of the cases of the series. The author did not find a single case in which it might be suggested that tuberculosis was the cause, contrary to the findings in other series of cases numerically greater. Local treatment consisted in the use of atropin ointment and, if the eye was not unduly irritated, 2 per cent. yellow mercuric oxid ointment. The local British product was mentioned specifically. Neoarsphenamin was used intravenously, an initial dosage of 0.12 gm. being increased a small amount each week for from ten to twelve weeks. Mercury was then prescribed, to be continued for about one year and in some of the older cases accompanied by iodid. In other words, the treatment advocated was the usual mild routine antisyphilitic treatment. The results were compared in terms of ultimate vision, the treated cases being compared with the untreated. The reports of the treated cases were extremely meager, as the vision was reported in only fourteen of the forty-seven cases. Without analyzing his figures, the author states that "comparison of these tables shows that the best results are obtained . . . by constitutional treatment." It is a nice booklet but unnecessary, for it does not add a thing to what is already commonly known.

Les rayons ultra-violets et associés en thérapeutique. Par Jean Saidman. Paper. Price, 65 francs. Pp. 580, with 194 illustrations. Paris: Gaston Doin, 1925.

Heretofore, information concerning the nature and action of ultraviolet rays and their therapeutic application has been scattered through various periodicals. This and the commercial propaganda carried on by manufacturers of ultraviolet apparatus have created a chaotic impression in the minds of physicians generally. In preparing this book, Dr. Saidman has sought to reestablish order by making information available, concerning not only the physical and photochemical characteristics of ultraviolet rays, but also their physiologic effects and their application to the treatment of disease. The book is divided into three parts, the first part dealing with the sources of ultraviolet rays; the second, with their physiologic action, and the third, with their therapeutic application. In the first part the author discusses the emission of ultraviolet rays by different substances, including the metals, the natural sources, and the various artificial sources. In discussing the latter, he gives a good account of the physical and other differences between the ultraviolet characteristics of the carbon arc lamp, as developed by Finsen, and of the mercury vapor lamp, including their advantages and disadvantages. This information is valuable, because it enables the reader to understand something of the controversy that has raged on this point. Reflectors, localizers, compressors and filters are likewise considered. There is an interesting chapter on the choice of a lamp, in which sound advice is given. The author warns that no reliance is to be placed on the claims of manufacturers, and that the choice must be based on the wave-length characteristics and on their adaptability to the effects desired. In the second part, the absorption of ultraviolet rays by air, by albumin and by tissues is discussed, as well as the photoelectric and chemical effects and the action of ultraviolet rays on bacteria. There is a chapter on the action of the ultraviolet rays on the skin, in which are described the various phases of actinic epidermitis, its symptoms and evolution, the effect of the actinic erythema on the general condition, the factors influencing the intensity of such erythema, and the influence of the erythema itself on the resistance of the skin. Separate sections are devoted to pigmentation, sensitization, and action on the blood, on the nervous system, on the eye, and on the deeper structures and organs. The third part is devoted to the technic of ultraviolet irradiation, both local and general; the instrumentation most suitable; the frequency of treatment; the measurement of ultraviolet rays; possible complications, and, finally, to a discussion of the different pathologic conditions in which ultraviolet rays are supposed to be useful. In criticism, it may be said that in the first chapter the nature of ultraviolet rays could have been described and explained more fully. Altogether, however, the book is a satisfactory one. The arrangement of the subject matter is logical. The experimental and clinical data are reviewed, and the author's opinions and conclusions, which are set off in italics, are clear. The book is well printed, well indexed, and contains a complete bibliography on the subject up to 1924. It constitutes a reliable work of reference for the research worker and for the physician who appreciates finding in such a work all the information available on the subject.

Die Individualität des Blutes in der Biologie, in der Klinik und in der gerichtlichen Medizin. Von Dr. Leone Lattes, Professor an der Universitat Modena. Paper. Price, 9.60 marks. Pp. 226, with 48 illustrations. Berlin: Julius Springer, 1925.

The first issue of this book in Italian appeared in 1923 and was received favorably. In the present edition the material has been revised and brought down to date; autoagglutination, complement binding iso-antibodies, the question of new iso-agglutinins, the heredity and the anthropologic significance of the blood groups are given expanded consideration. The references to the literature, which appear to be as complete as could well be expected, now number 700 in all, and especial pains have been taken to make them complete and correct. Blood groupage (isohemagglutination) is of interest in biology, anthropology, heredity and medicine, particularly surgery and medical jurisprudence, and the pertinent literature is scattered in periodicals representing all these departments of science. Lattes' book is the most comprehensive and the most satisfactory book on blood grouping. All the phases of the subject are presented thoroughly; a special chapter is given to the medicolegal use of blood grouping, and in an appendix to this chapter the translator, Fritz Schiff, discusses the method followed in Germany, which at present appears to be the only country in which the diagnosis of blood groups is used to throw light on questions of parentage, the individual source of blood spots, and similar problems for forensic purposes. The American work is given adequate consideration; the joint recommendation of the committee representing the American Association of Immunologists, the Society of American Bacteriologists, and the Association of Pathologists and Bacteriologists that the Jansky classification be adopted for universal use is cited with approval. The fact that in some places, as for instance the Mayo Clinic, a different scheme of classification is used is deprecated because it leads to difficulty in comparing the results of different workers and to misunderstanding in teaching and pratice.

ALLGEMEINE PATHOLOGIE. Von Dr. N. Ph. Tendeloo, Direktor des pathologischen Instituts der Reichuniversität Leiden. Second edition. Paper. Price, 66 marks. Pp. 1040, with 368 illustrations. Berlin: Julius Springer, 1925.

The training of the author for his task consists in part in service as assistant in pathologic anatomy followed by actual medical practice for eight years, when he became prosector and bacteriologist to the city hospital in Rotterdam and then professor in Leiden. The first edition of the work appeared in 1918 and before long demand arose for a new edition, which is now at hand. There are four parts: the first deals with general questions and conceptions, such as what is normal and abnormal, life and death, correlation and adaptation; the second part takes up general etiology and pathogenesis; the third part is devoted to local disturbances of nutrition, metabolism and function (hypertrophy, atrophy, degeneration, infiltration, inflammation, tumors); and the fourth part deals with general disturbances of nutrition, metabolism and function, and contains twelve chapters covering nearly 500 pages. This mere enumeration indicates the largeness of the scope of Tendeloo's General Pathology. The discussion is detailed, sound and scholarly, with possibly some tendency to diffuseness. The command of the literature seems remarkable and the list of the names of the authors cited in the text covers no less than twenty pages with three columns on each page; in addition, the most important basic works for each chapter are cited separately. The book will be a valuable and useful addition to the pathologic section of every medical library.

DIABETES, ITS TREATMENT BY INSULIN AND DIET. A Handbook for the Patient. By Orlando H. Petty, A.M., M.D., F.A.C.P., Professor of Diseases of Metabolism, Graduate School of Medicine, University of Pennsylvania, and William H. Stoner, A.M., M.D., F.A.C.P., Associate Professor of Biochemistry, Graduate School of Medicine, University of Pennsylvania. Second edition. Cloth. Price, $1.50. Pp. 133, with illustrations. Philadelphia: F. A. Davis Company, 1925.

Some good handbooks on diabetes have appeared recently; some have been insignificant. This one is both good and significant. The authors evidently give credit to the diabetic patient for having that understanding without which no handbook is of use. As a result the text, though plainly written, is real; the tables are decidedly helpful, and the recipes reliable.

SCHLAFMITTEL-THERAPIE. Von Dr. Albrecht Renner, Städtisches Krankenhaus Altona. Paper. Price, 4,50 marks. Pp. 125. Berlin: Julius Springer, 1925.

Modern chemical industry has almost hopelessly swamped the physician with a superabundance of hypnotics. To obtain the best effect from these agents, three factors have to be considered: the nature of the sleep disturbance, the nature of the diseased organism, and the nature of the hypnotic. A perusal of this scholarly treatise should enable the physician to fit the remedy to the case with as great a degree of scientific precision as our present knowledge permits.

Miscellany

MEMENTOES OF LAVOISIER

Notes on a Trip to Château de la Canière

GRAHAM LUSK
NEW YORK

I have elsewhere described my visit to M. de Chazelles, the great grandnephew of Lavoisier, at his apartment in Paris.[1] Since that publication, the old gentleman has passed away at an age well over 90 years. This summer I had the honor and pleasure of being most kindly received at the beautiful summer home of Madame de Chazelles at the château de la Canière, a few miles from Vichy and near Puy-de-Dôme at the beginning of the French Pyrenees. It was up Puy-de-Dôme, a mountain 4,800 feet above the sea level, that Blaise Pascal, in 1648, at the age of 25, caused a barometer to be carried and there demonstrated the diminution of the weight of the atmosphere.

When I was a student in Munich, Carl Voit told his hearers that he understood that the original respiration apparatus of Lavoisier was in a cellar in Paris and that, should he ever visit Paris, he would very much like to investigate the matter. He said that Lavoisier's technic was entirely unknown. This was about the time of the publication of Grimaux's "Lavoisier,"[2] which contained reproductions of two drawings by Madame Lavoisier showing the technic involved. These drawings picture Lavoisier himself actively experimenting and Madame Lavoisier sitting at a table, taking notes.

That part of the apparatus of Lavoisier now on exhibition at the Conservatoire des Arts et Métiers in Paris was evidently selected by chemists or physicists, and indeed I was told that I was the first physiologist to see the other collection of apparatus now housed in the château de la Canière. It seems that almost immediately after the execution of Lavoisier at the time of the French Revolution, his family recovered possession of his apparatus, his library and his original manuscripts. In witness of the tragedy is the broken lock of a beautiful morocco portfolio, which had been pried open by his accusers in their search for evidence against him.

It is related that the great chemist Dumas has read over the manuscripts. It may be that in this mass of papers is hidden a description of the method by which Lavoisier made the first measurements of "basal metabolism" on man and noted that this metabolism was increased by food, work and cold, for no physiologist has ever read them. Lavoisier was executed before he was able to publish his methods in full.

Professor Le Goff, the French friend through whom I was introduced to Madame de Chazelles, and I reverently examined each bit of apparatus. We could compare the apparatus with the pictures drawn by Madame Lavoisier. We found the glass globes, the tall cylinders with petcocks at one end. There was a cork valve in a copper cylinder, indicating that a light air valve might have been constructed for use in the oblong box shown nearest the face mask in the second drawing of Madame Lavoisier (Grimaux, p. 128). Diligent search, however, failed to reveal this particular oblong box.

The surprise of the visit was the discovery of the original face mask used on the subject Seguin. The face mask was of copper and was fitted with two glass eyes similar to those used in diving bells. The mask continued so as fully to cover the nose. For some unknown reason, the nose of the mask is now perforated with holes. The edge of the mask was perforated for binding on the head. Probably the tube into which Seguin breathed was introduced through either leather or rubber, which fell down from the nose piece of the mask and was fitted around the neck and around the head of the subject. We saw a large rubber bulb that had been used by Lavoisier, so the material must have been known to him.

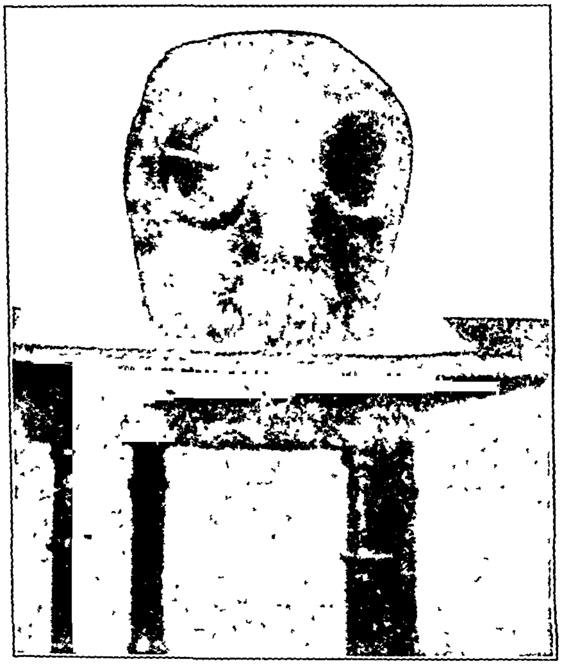
---

[1] Lusk, Graham: Some Influences of French Science on Medicine, Proc. Inst. Med. Chicago 3:98, 1921.

[2] Grimaux, E.: Lavoisier, Paris, 1888.

Now it curiously happened that a few weeks after seeing this mask I was at Davos, and Prof. A. Loewy, the head of the alpine laboratory there, showed me a new, as yet undescribed respiration mask covering the whole head, which was almost the exact duplicate of what Professor Le Goff and I a few weeks earlier had concluded must have been the device employed by Lavoisier 140 years ago.

Other interesting objects that we saw were a simple laboratory chair with an elongated arm, made perhaps for convenience in taking the pulse rate, and a watch that not only registered the time by the twelve hour half day, but also simultaneously showed the time according to a new ten hour day. The Lavoisier library contained presentation copies from Laplace and many another treasure. And there were three small portraits of Count Rumford (Benjamin Thompson), a great friend of Lavoisier.



Copper mask used by Lavoisier in his estimation of the respiratory metabolism of man.

A bust of Lavoisier by Houdin and a very large rosewood desk used by Lavoisier were in the main hall of the château A magnificent Empire bedroom suite given to Madame Lavoisier on the occasion of her unfortunate second marriage to Count Rumford indicated the splendor surrounding the lives of the aristocratic families of that time.

Among many drawings by Madame Lavoisier is one on which is written in the hand of her teacher David, "Très bien, très bien, très bien." The picture of Lavoisier and his wife painted by the great master David, the only portrait of him in existence, a treasure of surpassing worth, is now in an American home. A kindly Frenchman wrote me that he was glad to hear that it was in the hands of "your good countryman, Mr. J. Rockefeller, so devoted to the medical researches." To those who know what Mr. Rockefeller has done for the restoration of the Cathedral of Rheims and of the palace of Versailles, for the benefit of man now and in centuries to come, it will be gratifying to know that this great picture is held in trust by him.

Barred Evidence Against Roentgenologist—of Blood Test

(Unger v. Grimsley (Miss.), 103 So. R. 341)

The Supreme Court of Mississippi, Division A, says that plaintiff Grimsley brought this action to recover damages for a burn alleged to have been caused by the defendant's negligence and unskilfulness in applying roentgen rays to the plaintiff's hip. During the cross-examination of the defendant, and over his objections, he was required to testify in regard to an alleged roentgen-ray burn inflicted by him on another person two years after the alleged burn of the plaintiff. It was shown that the second burn was inflicted under entirely different circumstances, and with a different machine. The court thinks that testimony was inadmissible and highly prejudicial. The testimony in this case was in sharp conflict as to the number of exposures, and the length of those exposures, and the court thinks that on the testimony in the record the case was one for the jury; but for the error in admitting testimony of a subsequent burn of another person, the judgment of the court below for $2,000 in favor of the plaintiff must be reversed, and the cause remanded

As to the contention of the defendant that the testimony of the director of the state hygienic laboratory, as to the contents of certain records of his office showing the result of a certain blood test, was admissible as a public record, under provisions of the code, the supreme court expresses no opinion, since it was not shown that the proffered testimony pertained to a blood specimen of the plaintiff, and consequently it was for that reason inadmissible

Insufficient Allowance for Medical Treatment

(Baker v. Rundquist et al. (Minn), 203 N. W. R. 452)

The Supreme Court of Minnesota says that the plaintiff while in the employ of the defendant sustained lacerated wounds on the right side of his face affecting his right eye. He was entitled to compensation. First aid was given by a local physician for ten days No examination was made of the internal nasal region. Later the plaintiff consulted a specialist, who treated him. The referee allowed $9 for first aid. No further sum was allowed for medical attendance. Disability compensation, under the workmen's compensation act, was allowed for five weeks and three days. An examination of the evidence leads the court to the conclusion that the plaintiff was entitled to medical services additional to his first aid attention. He said that he had internal trouble in the nasal region. The physician who gave first aid treatment was not a specialist and gave treatment for the superficial wounds only. The specialist gave treatment, and he thought it was needed. It might be that some of the work done was not required by the injury. In any event the workman was entitled to exploratory treatment, and perhaps to all that he received. The charges made by the specialist might be high, but this court is not concerned with them now. Furthermore, as a matter of law the plaintiff's disability did not cease at the end of five weeks and three days. It was not long continued, but it did not cease so soon. The amount of the award should be reconsidered. It could not be large. The situation invited a settlement rather than further litigation.

Weakened Resistance an Injury—Pneumonoconiosis

(Kozaliski v. Collins Co. et al. (Conn.), 128 Atl R. 288)

The Supreme Court of Errors of Connecticut, in holding that there was no error in a judgment affirming an award for the plaintiff, under the workmen's compensation act of that state, says that the compensation commissioner found that the plaintiff, who had been employed as a grinder, had received a personal injury consisting of pneumonoconiosis, which had developed into a mixed infection of a tuberculous, staphylococcic and streptococcic nature. The compensation act provides that if an injury arises out of and in the course of the employment, it shall be no bar to a claim for compensation that it cannot be traced to a definite occurrence which can be located in point of time and place; also, that the word "injury" shall be construed to include any disease which is due to causes peculiar to the occupation and which is not of a contagious, communicable or mental nature. The defendants contended that the plaintiff having grinder's consumption, and that as that is a form of tuberculosis and tuberculosis is a contagious or communicable disease, therefore it was not compensable under the statute. But the injury that developed into grinder's consumption was a weakened resistance to infection called pneumonoconiosis. This was an injury not contagious or communicable; hence the statute did not bar a recovery, when it became a compensable injury by infection causing incapacity. The character of the plaintiff's work as a grinder injured him by producing a condition of the lungs which offered weakened resistance to staphylococcus infection, to streptococcus infection, or to infection from the tubercle bacilli. His injury was the condition of weakened resistance to infection, and when such a condition of weakened resistance yields to infection and makes the workman unfit to work, the injury has become a compensable one. The consequent effects of the weakened resistance to infection in this case, namely, the infection producing grinder's consumption, was not the injury compensated for; it was the weakened resistance to infection which was the injury compensated for; the consequences of that condition when infection occurred was deemed a part of the weakened resistance to infection. The injury occurred when the condition of weakened resistance arose. When the injury (the weakened resistance to infection) arises in the course of and out of the employment, then every consequence that flows from it likewise arises out of the employment.

No Prohibition Against Issuing Prescriptions

(Aiton v. United States (U. S.), 3 Fed. R. (2d Series), 992)

The United States Circuit Court of Appeals, Ninth Circuit, in reversing a judgment of conviction of defendant Aiton and in doing it with instructions to sustain a demurrer to the indictment and quash the latter, says that it need consider only the one count of the indictment on which the conviction was had. That count charged that the defendant, who was a practicing physician and duly registered with the collector of internal revenue, did unlawfully issue and write and deliver a prescription to a named person for 56 grains of morphin sulphate, not in good faith for meeting the needs of said person and not to effect a cure of him in the course of professional practice only, said person being a habitual user of and addicted to the use of narcotic drugs, nor to treat said person then and there suffering from an incurable or chronic disease, in the course of his professional practice only, but, on the contrary, with the intent and purpose to dispense, distribute, barter and sell such narcotic drugs for the purpose of catering to and satisfying the cravings of said person for said drug. The indictment stated on its face that it was based on Section 1 of the Act of Dec. 17, 1914 (the Harrison Narcotic Act), but the government conceded that the reference should have been to Section 2. However, it would be as difficult to sustain the indictment under the latter section as under the former. Section 2 only prohibits the sale, barter, exchange, giving away, dispensing or distribution of drugs, except in certain cases not material here. There is no prohibition in that section or elsewhere in the act against issuing, writing or delivering prescriptions by a physician, regardless of the intent of the physician or the purpose for which the drugs are to be used.

It was to be inferred from the language of the indictment that it was based on the decisions in *United States* v. *Doremus*, 249 U. S. 86, 39 Sup. Ct. 214, and kindred cases, in which indictments were sustained by the supreme court. But it will be found on examination that in every such case, except where a conspiracy was charged, the indictment charged a sale or other distribution of drugs, and that in the conspiracy cases the charge was a conspiracy to sell or distribute drugs, not a conspiracy to issue, write or deliver prescriptions. For these reasons the count of the indictment under consideration charged no crime, and the demurrer should have been sustained.

"Practice of Medicine and Surgery" by Chiropractor

(State v. Morrison (W. Va.), 127 S. E. R. 75)

The Supreme Court of Appeals of West Virginia, in affirming a judgment of conviction of the defendant for practicing medicine and surgery as defined by Section 8a, Chapter 150, in the 1923 code of that state, without first having obtained a state license to do so, says that the weight of authority is to the effect that one who practices the chiropractic art or science comes within the provisions of a statute regulating the practice of medicine. Said Section 8a provides that the term "practice of medicine and surgery" as used by the West Virginia statute shall be construed to be the "treatment of any human ailment or infirmity by any method"; and that "to open an office for such purpose or to announce to the public in any way a readiness to treat the sick or afflicted, shall be deemed to engage in the practice of medicine and surgery within the meaning of this act." One who opens an office and announces to the public in any way that he is ready to treat the sick and afflicted, and has actually treated cases of paralysis, constipation, rheumatism, neuritis, sick headache, kidney trouble, lumbago, liver trouble, and divers other diseases by adjustment of the segments of the spinal column according to the chiropractic method of treating human ailments and infirmities, this court holds is "practicing medicine and surgery" as defined by said section.

The scope of the definition of the practice of medicine and surgery in Section 8a is too broad, its terms too explicit, and the intention is too plain to allow it to be modified and restricted by the former legislation. The mere fact that a school of medicine is not specifically mentioned does not in itself evidence an intention of the legislature to exclude it from the operation of the statute, if from a consideration of all its provisions the contrary clearly appears. The legislature cannot be expected to anticipate the founding of new methods of healing. It has by this statute evidenced its intention to regulate the practice of all medicine and surgery.

Nor does the court agree with the defendant's contention that, if the statute be construed to require him to pass an examination on the science of medicine, drugs and materia medica, as recognized and taught in Class A medical schools, or on the methods or practices peculiar to surgery as therein taught in order that he might lawfully practice his method of treatment of human ailments and diseases, then the statute would be unconstitutional and void as depriving him of the pursuit of a lawful calling as a means of acquiring property and obtaining happiness and safety. The statute does not contravene any of the rights of the defendant guaranteed to him by the West Virginia and the federal constitutions. It is undoubtedly true that the privilege of engaging in the practice of medicine is a valuable property right protected by constitutional guarantees. But the preservation of the public health by the sovereign power is paramount to the exercise of the private privilege by the individual, and consequently the state has the inherent right by means of its police power to impose such reasonable restrictions on the practice of medicine as are deemed necessary to attain the end in view, the preservation of the public health.

Society Proceedings

COMING MEETINGS

American Academy of Ophthalmology and Otolaryngology, Chicago, Oct. 20-24. Dr. Luther C. Peter, Chestnut and 20th Streets, Philadelphia, Secretary.

American Association of Railway Surgeons, Chicago, Oct. 21-23. Dr. Louis J. Mitchell, 29 East Madison Street, Chicago, Secretary.

American College of Radiology and Physiotherapy, Chicago, Oct. 19-22. Dr. Roy W. Fouts, 121 South 33d Street, Omaha, Neb., Secretary.

American College of Surgeons, Philadelphia, Oct. 26-30. Dr. Franklin H. Martin, 40 East Erie Street, Chicago, Director-General.

American Public Health Association, St. Louis, Oct. 19-22. Mr. Homer N. Calver, 370 Seventh Avenue, New York, Executive Secretary.

Central Neuropsychiatric Association, Ann Arbor, Oct. 23-24. Dr. Karl A [illegible] nic, Topeka, Kan., Secretary.

Central [illegible] November 6-7. Dr. H. T. Price, [illegible] Secretary.

District of Columbia, Medical Society of, Washington, D. C., Dec. 2. Dr. C. B. Conklin, 500 Medical Science Bldg., Washington, D. C., Sec'y.

Radiological Society of North America, Cleveland, Dec. 7-11. Dr. Robert J. May, St. Luke's Hospital, Cleveland, Secretary.

Southern Medical Association, Dallas, Texas, November 9-12. Mr. C. P. Loranz, Empire Bldg., Birmingham, Ala., Secretary.

Current Medical Literature

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL for a period of three days. No foreign journals are available prior to 1920, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

Diphtheria: Review of Literature for 1924. T. T. Crooks, Chicago.—p. 367.

Low Basal Metabolism in Postinfectious States.—Schick and Cohen assert that many patients with acute infections in their postinfectious state have a low basal metabolism. This low metabolism usually lasts for a few days, in some cases for a few weeks. The usual curve of the basal metabolism in the postinfectious state begins with a low figure, rising to normal in about one week. Two patients with meningeal conditions had a low basal metabolism for weeks, coincident with a low pulse. In one case, the basal metabolism and the pulse rate rose to normal simultaneously. Usually there is a good correlation between the pulse and metabolism. The authors believe that a slow pulse is a good clue to the finding of a low metabolism, especially if the heart is of normal size. In the cerebral diseases in which extraneous factors have the least influence on the pulse rate, a slow pulse rate and a low basal metabolism were found in two reported cases and also in one case of a protracted post-pneumonic bradycardia. The rise of metabolism and the increase of the pulse rate occurred together. The authors believe that the slow pulse at postinfectious states of certain brain diseases and of icterus is caused by a low basal metabolism and not by a stimulation of the vagus, at least in most instances. A theory is outlined which attempts to explain the low basal metabolism in these conditions.

Energy Metabolism of Premature Infants.—Energy metabolism has been determined by Marsh and Murlin in eighty-two observational periods on twenty-one premature and undersized infants, including five pairs of twins. The average basal respiratory quotient was low (0.74) through the fifth day, rose to 0.79 on the sixth day but never above this figure through the ninth day; whereas the quotient for a child in good nutritive condition, at least after the first week, should be about 0.85. The basal metabolism of these twenty-one infants averages 6.48 calories per hour, or 26.25 calories per square meter (Lissauer) and 2.04 calories per kilogram per hour. When the basal metabolism per square meter is averaged according to days of age there is a fluctuation during the first week, the lowest value coming on the seventh day with a higher value on the eight and ninth days. Each day the metabolism is definitely lower than for the value obtained for normal babies born at term. Increases in heat production with activity varies from 2.5 per cent. with slight restlessness, to 40.3 per cent., when the child cried 39.0 per cent. of the time. In a limited number of periods and all on infants one month, or less, premature, the observation made previously for full-term babies; that is, crying 1 per cent. of the time increases the metabolism 1 per cent., seems to hold fairly well. An increase of 42.1 gm. of food increased the metabolism 5.19 calories per square meter per hour, or 21.3 per cent.

Nitrituria.—Greenthal has found a positive nitrite reaction in freshly passed urine at times in about 50 per cent. of cases of pyuria due to nitrate-reducing organisms. A positive reaction is valuable as an aid to diagnosis, but a negative reaction has no significance. The failure of the nitrite test in these cases is due chiefly to a lack of nitrate in the urine. A modification of the Griess-Ilosvay test for nitrituria is presented.

Fatal Diabetes in Infant.—Notwithstanding temporary improvement in every respect under insulin treatment, Schippers' patient died in coma at the age of 25 months.

External Obturator for Nostrils in Cleft Palate.—Foote stops the nostrils with a simple strip of dental rubber dam about 2 inches wide and 4 inches long, to which are attached tapes at each side in the longest diameter. This is placed over the infant's nose, and the tapes are tied so that the rubber is stretched with sufficient tightness to block off the nostrils, the lower end of the rubber dam lying over the lip and the nipple. This obturator effectually excludes air.

Nitrogen and Mineral Balances in Infants.—A comparative study of the calcium, phosphorus and nitrogen balances has been made by Daniels and Stearns in infants receiving cow's and goat's milk feedings, respectively. Milk from two goats, having a somewhat different composition, was tested separately. The urinary phosphates in all infants receiving goat's milk was higher than during the periods when they were receiving cow's milk, even though the phosphorus ingested (in two cases) was no higher than in the corresponding periods when they were receiving cow's milk. The calcium and phosphorus balances during the goat's milk periods did not indicate that the inorganic moiety of the goat's milk was superior to cow's milk. Nor did the ratio of phosphorus to calcium retained by infants receiving goat's milk suggest that this is better than cow's milk. On goat's milk all infants retained considerably less nitrogen (from 17 to 25 per cent in one series and from 42 to 44 per cent. in another) than during the corresponding period, when they were receiving cow's milk.

Tuberculoid.—Tobias favors the term tuberculoid, advocated by Darier, for the condition known as tuberculid as being a more appropriate designation.

Skin Hypersensitiveness to Tuberculin.—For four and a half years Andrus has employed tuberculin intracutaneously more or less as a routine measure. This study is based on an analysis of 1,728 tests on an even 1,000 adult admissions. The majority received tests shortly after admission, and many were tested at varying intervals during residence and at discharge. Of these patients, fifty-eight were considered to have nonactive pulmonary tuberculosis, and not to require treatment; 114 were diagnosed nontuberculous, although the majority of them had chronic pulmonary or bronchial affections, and the remainder were considered to have active pulmonary or bronchial affections, and to be in need of treatment. In this series the presence of the general tuberculin reaction (as indicated by fever) has no constant bearing on the degree of tuberculin skin hypersensitiveness. The degree of tuberculin skin hypersensitiveness offers no clue to differentiate active from nonactive pulmonary tuberculosis in a clinical way. In the absence of definite tuberculous involvement, negative tuberculin skin tests would tend to throw the balance of evidence in favor of a nontuberculous diagnosis. In tuberculosis diagnostic problems the presence of well marked tuberculin skin reactions would tend to throw the balance of evidence in favor of a tuberculous diagnosis. The earlier and more favorable types of tuberculosis tend to the higher levels of tuberculin skin hypersensitiveness, and the more advanced and less favorable types to the lower levels. No characteristic changes in degree of tuberculin skin hypersensitiveness occur during the favorable progress of tuberculous disease. Changes occur one way or the other in about 40 per cent. of cases relatively early and then tend to maintain a constant level. The level of tuberculin skin hypersensitiveness rises in 50 per cent. of tuberculous individuals at the time of relapse. The data as offered by degree of, or changes in, tuberculin skin hypersensitiveness are of small practical value in the clinical estimation of a given case.

Dreyer's Antigen.—Some observations made by Boissevain on the defatted *B. tuberculosis* antigen of Dreyer are reported. His observations do not justify any inferences regarding the effect of the antigen on chronic experimental tuberculosis. Two patients with far advanced pulmonary tuberculosis have, at their own request, been treated with the same antigen. The treatment, continued now for about eight months, has not shown any notable effects, either favorable or unfavorable.

Tuberculo-Complement-Fixation and Inhibitive Tests. — The results obtained by Caulfeild, Hodge, MacLennan, LaRush, Ogden, MacIntyre, Anglin and Cohen by carrying out two serologic tests periodically during several years' observation on "normals," contacts and cases of tuberculous and nontuberculous disease have been classified and given in percentages. From these an approximate diagnostic value can be drawn. Among the normals there was serologic evidence for suspecting the presence of tuberculous lesions in twelve, and this was subsequently confirmed in two by at least two other methods of investigation. Among the contacts there were similar grounds for suspecting that the exposure had resulted in an implantation of the bacilli in over 40 per cent. Among the cases the tests were helpful in estimating the probability of tuberculosis as a correct diagnosis, and among the definitely tuberculous in vizualizing the progress frequently before there were appreciable clinical evidences of a change in the course of the disease. The tests will not give a satisfactory short cut (laboratory) diagnosis for or against tuberculosis. If this is demanded the results will be disappointing or misleading because (*a*) the tuberculin complement fixation reaction is negative in a considerable percentage of the tuberculous; (*b*) because it is at least weakly positive in a large number who are evidently not tuberculous; (*c*) because the inhibitive test can consistently be normal in a large percentage of the definitely tuberculous, and (*d*) because an occasional case will give a positive inhibitive test in which there will be no grounds for suspecting clinical tuberculosis.

Effect of Bismuth on Wassermann Reaction.—The effect of bismuth on the Wassermann antibody in the so-called Wassermann-fast patients, who do not respond serologically to arsenic and mercury is discussed by Belding. Bismuth treatment lowers the strength of the Wassermann antibody not only in patients who are responsive to arsphenamin, but also in those who are unresponsive. The average reduction in the series studied by Belding composed largely of arsphenamin-resistant patients, was 39 per cent. which probably represents the minimum effect of bismuth. Nine tenths of the reduction was obtained four weeks after the end of treatment, and the remaining one tenth by the sixteenth week. In patients with old syphilis, bismuth does not give any slower serologic action than the arsphenamins. The reduction appears permanent, at least it was permanent for the six months the patients were under observation. The few patients who showed a relapse received less than the standard dosage. Variable factors such as the strength of the reaction, the clinical stage and duration of the disease and the total dosage, which usually render serologic interpretations of doubtful value, exerted a negligible influence in this particular series and permitted direct comparison between patients responsive and unresponsive to arsphenamin. However, the extent of the reduction of the Wassermann antibody corresponded to the intensity of treatment. All the Wassermann-fast patients in this series had shown no change in the strength of the Wassermann antibody under treatment with arsphenamin. One half of these patients reacted to bismuth as compared with five sixths of the patients who were responsive to arsphenamin. Also the quantitative reduction of the Wassermann antibody in these patients was one half that of the arsphenamin responsive patients. After the first course of treatment the total amount of arsphenamin and mercury given had no apparent influence on the action of bismuth.

Sigma Reaction for Syphilis.—Smiley regards the sigma reaction as offering a reliable index in following the effect of a course of treatment for syphilis. The validity of the sigma reaction is apparently not affected by treatment. Much more information can be gained from a course of sigma readings than from a similar course of Wassermann readings.

Nitritoid Crisis Following Intravenous Injection of Arsenicals.—It was observed by Müller that the patients who reacted to arsphenamin with unusual symptoms of a nitritoid crisis and those who showed equally unusual symptoms after injections of silver arsphenamin, i. e., a decrease in the number of leukocytes in the blood with or without visible manifestations, will also react positively to the Widal test without showing any apparent sign of hepatic involvement. Müller is convinced that the unusual reaction in the blood following injections of silver arsphenamin into patients who also show symptoms of a nitritoid crisis after administration of arsphenamin is not due to the drug, but rather to a pathologic reactivity of the involuntary nervous system. This abnormal reactivity, latent in the body before injection and manifested by an unusual reaction of the body itself, is due to a disturbance of the involuntary nervous system.

Universal Psoriasis and Tumor-Like Lesions.—Report is made by Levin of a case of universal psoriasis complicated by the presence of what the author considers a hitherto undescribed feature of tumor-like lesions. The tumors showed a pathology which differed in no way from that observed in a typical case of psoriasis; and the microscopic findings of the tissue from the general eruption and the infiltrated strands on the thighs were similar to those seen in the tumor growths, differing only in degree of hypertrophy of the rete pegs, the infiltration and the intensity of the edema. The tumor growths were even more edematous than was shown under the microscope, and it was concluded, therefore, that the tissue must have contracted considerably by means of the chemicals and heat during the preparation of the slides. The strandlike, elevated infiltrations of firm and doughy consistency on the thighs, and the involvement of the lips and nails were also unusual features. The characteristic clinical lesions and tumors both disappeared subsequent to autoserotherapy, and on cessation of this form of treatment, the lesions recurred. Autohemotherapy caused a slight involution of the lesions, thus modifying the eruption, but no radical change was produced by this form of treatment.

Lichenoid Sarcoid.—The case reported by Wright presented a most unusual form of sarcoid; it appeared first as areas of loss of pigment in which lichenoid plaques developed The condition was associated with pulmonary tuberculosis, which apparently developed four years after the appearance of the cutaneous manifestations.

Glioma of Bulb and Pons; Four Cases P Bassoe and C W Apfelbach, Chicago —p 396

Relation of Thalamus to Mind.—In summing up his consideration of the rôle of the thalamus in the physiology and pathology of mind, Dercum points out that while in the interaction of the thalamus and cortex, the cortex is normally dominant, the thalamus controls the gateways of admission and in diseased states may hold the cortex at its mercy. While the nuclear aggregations of the thalamus are undoubtedly influenced by the internal secretions, the thalamus in its turn contains centers which profoundly influence metabolism These centers are situated in the floor of the hypothalamus and are probably in close relation with the visceral nuclear aggregations and have to do with the reactions of the latter on each other That the resulting emissive streams should in turn influence the activities of the viscera, and among these especially the glands concerned in anabolic and catabolic changes, is, perhaps, what should naturally be expected.

Effect of Hypertonic Solutions Administered Intravenously on Cerebrospinal Fluid Pressure.—Experiments have been made by Howe to determine the effect of the intravenous administration of various hypertonic solutions on the cerebrospinal fluid pressure of cats Concentrated solutions of sodium bicarbonate, sodium sulphate, sodium citrate, sodium chlorid, sodium bromid, calcium lactate, calcium chlorid, magnesium sulphate and dextrose have been used A few observations with a combination of electrolytes have also been made in the proportions given in the Ringer-Locke and Tyrode solutions Sodium bromid, calcium lactate, calcium chlorid and magnesium sulphate were found to be too toxic Sodium citrate, sodium tartrate and sodium bicarbonate were relatively ineffective Sodium sulphate, sodium chlorid, concentrated Ringer-Locke solution and concentrated Tyrode solutions and dextrose produced satisfactory depressions Sodium sulphate was nontoxic at first but has been reported by Weed and McKibben to have caused death later, and so is unsafe for clinical use Sodium chlorid produced the most pronounced decrease in intracranial pressure of any substance used, but it is toxic unless administered very slowly Furthermore, as it is later mobilized in the tissues producing a secondary wave of edema, as shown by Fay, it is considered unfit for general clinical administration The same objections apply to concentrated Ringer-Locke and Tyrode solutions although they are somewhat less toxic Dextrose is the only substance of this group which is nontoxic and produces a satisfactory fall in intracranial pressure

Intracranial Dermoid Cysts—Rand reports a case of intracranial dermoid cyst The wall resembled true dermis containing hair follicles, sweat glands and stratified squamous epithelium The central mass was filled with debris composed of desquamated cells, among which were scattered fine hairs and cholesterin crystals It was attached to the dura in the left temporal region and should probably come under the classification of "meningeal cholesteatoma" suggested by Horrax The outcome of the case was disappointing The cyst became infected after its first opening, and its ultimate complete removal was followed by local meningitis and brain abscess, to which the patient succumbed

Determination of Spinal Fluid Sugar.—Fremont-Smith and Dailey insist that spinal fluid sugar should be determined on patients fasting, preferably over night, and compared with coincident blood sugar

*Sporotrichosis, Case from Pennsylvania F C Knowles, E F Corson and H B Decker, Philadelphia —p 835

Mercurochrome Treatment of Chronic Otorrhea.—In the treatment of these cases Wagers uses mercurochrome, 5 per cent in 50 per cent alcohol, dropped into the canal and middle ear, the head resting on the side The canal is tightly plugged with cotton to prevent the outflow of the solution, which stains the skin. Of the forty-five ears treated, twenty-three, or 51 1 per cent, became dry after an average of 6 5 applications Sixteen cases were recorded as improved; six were not. Eight definitely dry ears were secured in a series of 162

Sporotrichosis in Pennsylvania.—Six cases of sporotrichosis have been observed in Pennsylvania in which the fungus has been cultured and isolated The seventh case is reported by Knowles, Corson and Decker

Goiter.—Endemic goiter is composed of colloid and adenomatous elements. In early life the colloid element predominates; after 25, the adenoma predominates. These changes are progressive and constant and in time, the length of which is well established, will cause the appearance of symptoms. Coller shows that frank hyperthyroidism caused by endemic goiter will be found to increase in frequency from the latter part of the third decade to the fifth and sixth decades when at least a third of the cases will have it. Definite cardiovascular damage will appear in at least a quarter of the cases with hyperthyroidism and in a smaller, but appreciable, number of cases with normal metabolic rates. Endemic goiter is a precancerous lesion with an incidence of malignancy of at least 3 per cent. Endemic goiter causes many mental changes of a minor, but disabling, nature and in those with a psychopathic inheritance may excite the appearances of some mental abnormalities. The progressive nature of the goiter pathology and the appearance of symptoms makes it possible to attack the goiter at a time when medication has ceased to be effective and when the changes begin to menace the health of the patient. The surgical removal of the adenomatous goiter at this time will prevent the appearance of the great morbidity otherwise to be expected. The removal of adenomatous goiters should be advised on diagnosis in individuals after the age of 25.

Management of Rabies Outbreak.—In consequence of five cases of canine rabies developing in Milton, Mass., during the first few weeks of 1925, the board of health carefully reviewed the whole question of the prevention of this disease. It at first offered voluntary inoculation of dogs at which only about 18 per cent. of the dogs were immunized. Then in the presence of growing popular interest, choice of restraint, muzzling, or inoculation was ordered. There was some difference of opinion as to whether under the existing law muzzling had to be offered as an alternative but there was no doubt of its utter futility. In the end about 41 per cent. of the dogs were immunized. Efforts to enforce restraint met with the customary indifferent results. As quarantine of any common communicable disease in a given community is in general no better than public opinion demands, so the quarantine of dogs to which public opinion was largely indifferent was indifferently enforced. This is the conventional situation and suggests that more and more dependence must be placed on active immunization to protect communities against the ravages of rabies. Withington and Bigelow are of the opinion that it is practical to require inoculation as a prerequisite to licensing dogs, as advocated in New Jersey.

Sporothrix Infection of Large Intestine.—Boggs and Fried relate the occurrence of an acute and severe dysentery associated with the presence of a sporothrix-like organism in the stools in great numbers, and the clearing up of the condition coincidently with the destruction of the organisms by an antiseptic dye, thus seemingly justifying the tentative association of these as cause and effect. This is further strengthened by the fact that the organism belongs evidently to a group which has furnished pathogenic strains affecting the lungs, skin and lymph glands in numerous reported cases from widely scattered regions of the world. Additional interest is given this case from the association of a mycotic infection of the finger-nails for years preceding the acute intestinal infection with the same organism. It is conceivable, at least, that the patient had taken spores into her intestinal tract for years as a result of biting her nails, and that some incidental factor may have determined the implantation of the organism on the intestinal mucosa. This factor may have been a change in the intestinal resistance, through traumatic or toxic agencies, or an alteration in the virulence in the organism itself.

Blood Changes Resulting from Intravenous Glucose Injections.—Certain blood changes resulting from the injection of large quantities of glucose solution are described by Smith. The blood volume changes indicated by the dye method agree quite well with changes indicated by alterations in hematocrit and hemoglobin. Reasons are given for the failure of Lamson and Rosenthal to obtain concordant results in somewhat similar infusion experiments.

Diaphragmatic Hernia.—White cites a case of right-sided diaphragmatic hernia containing the liver, gallbladder, hepatic flexure of the colon and omentum. The case is complicated by a chronic ulcer in the esophagus, chronic empyema, acute pericarditis and a peculiar type of malignant tumor. From the history and necropsy findings a theoretic explanation is advanced for the formation of the hernia, but the exact classification and point of origin of the tumor could not be determined.

Elimination of Sugars in Phlorhizin Diabetes.—A study made by Deuel and Chambers of the hourly elimination of extra glucose, fructose and galactose in fasting phlorhizinized dogs showed rates practically identical. Lactose, on the other hand, was excreted much more slowly, and less than 50 per cent. of extra glucose arising therefrom was recovered at the end of twelve hours. The glucose originating from fructose represents a 100 per cent. conversion from the carbohydrate ingested and was almost completely eliminated in five hours. The conversion of galactose to glucose has been shown to be nearly quantitative, 98 per cent. of the theoretical amount being excreted as extra glucose. A sparing action on nitrogen metabolism has been noted in each case in which there was increased glucose excretion irrespective of its source, although the glucose was not utilized and was quantitatively excreted.

Metabolism of Glycerol in Phlorhizin Diabetes.—A practically complete conversion of glycerol to glucose was noted by Chambers and Deuel in two phlorhizinized dogs. After the ingestion of 8.53 gm. of glycerol, 96.9 and 98.4 per cent., respectively, of extra glucose were recovered in the urine. A third dog yielded 55 per cent. conversion after ingestion and 70 per cent. after subcutaneous injection of glycerol. A decrease in the respiratory quotient from 0.703 to 0.678 after giving glycerol, indicates that there was no general oxidation of the ingested glycerol, which has a respiratory quotient of 0.86, nor of the glucose into which it was converted. The reduction in the respiratory quotient from 0.703 to 0.678 may be exactly accounted as due to the oxidation of the 2 atoms of hydrogen liberated in the reaction glycerol → ½ glucose. In the rate of excretion and the sparing of protein metabolism the reaction of glycerol was similar to that of the monosaccharids.

Blood Sugar Time Curves Following Ingestion of Dihydroxyacetone.—It has been shown by Rabinowitch that the diabetic is apparently able to tolerate dihydroxyacetone more readily than glucose. This substance has now been tested out in a number of cases of diabetes. When dihydroxyactone is administered by mouth in proper dosage it has an insulin-like action in that it lowers the blood sugar. It is thus not only more readily tolerated than glucose by the diabetic, but actually has some influence on the metabolism of the carbohydrates already present in the body. Rabinowitch has substituted dihydroxyacetone for doses of insulin without, as previously, deducting a corresponding quantity of other carbohydrates from the diet.

Nutritional Anemia on Whole Milk Diet.—Rabbits limited to a whole milk (cow's) sodium citrate diet, Hart, Steenbock, Elvehjem and Waddell found will develop a nutritional anemia characterized by low hemoglobin and erythrocyte contents of the blood. Inorganic iron added to the basal ration will not per se correct this anemia. Inorganic iron in the presence of fresh cabbage or an alcoholic extract of desiccated cabbage or an alcoholic extract of yellow corn meal will prevent or cure such an anemia. These extracts are free from iron. Chlorophyll, free from iron, will also, in the presence of added inorganic iron, correct such an anemia as is induced by a whole milk-sodium citrate diet. The relation of these substances to vitamin E and to certain recent investigations on the nutritive properties of milk are discussed.

Betaine Fraction in Alfalfa Juice.—A fraction containing the quarternary bases has been obtained by Vickery from the juice of the alfalfa plant. This fraction contained 8.48 per cent. of the nitrogen of the protein-free juice of the plant (the "alfalfa filtrate") and nearly 81 per cent. of this nitrogen has been accounted for as stachydrine, chlorin, trimethylamine and betaine.

Experimental Rickets; Pure Foodstuff Diet.—In these experiments McCollum and his associates made use of a diet composed principally of purified foodstuffs for use with the "line test" for vitamin D studies. The formulas of two diets are given.

Concentration of Inorganic Substances in Serum and Spinal Fluid.—In a series of seventeen cases of epilepsy Hamilton found normal concentrations of chlorid, bicarbonate, inorganic phosphorus, total fixed base and calcium in serum and spinal fluid. The correlation between the chlorids in the serum and the chlorids in the spinal fluid was not very marked. A close relationship was found between the bicarbonates in the two fluids. The correlation between the values for calcium was fairly good and was somewhat less close between the values for inorganic phosphorus. Monovalent base showed about the same low degree of correlation as the chlorids and probably for the same reason.

Parathyroid Hormone Relieves Tetany.—Hjort, Robison and Tendick extracted a hormone from fresh bovine parathyroid glands by aqueous or alcoholic hydrochloric acid extractions which when given parenterally to dogs possesses the property of relieving tetany and inducing hypercalcemia.

Determination of Calcium in Milk.—Rothwell has devised a method of determining the calcium in cow's milk by direct precipitation with ammonium oxalate, without removal of protein.

Metabolism of Women.—On the basis of a total of more than 300 determinations of "before breakfast" blood sugar, covering forty-nine menstrual periods in twenty-six normal women, Okey and Robb state that there seems to be no ground for the conclusion that there is a consistant cyclic variation in the fasting blood sugar level in women. The average values observed during menstruation are slightly higher than those for the intermenstrual period. However, there are a greater number, not only of high values, but also of low values, during the menstrual period than at any other time. Hence, it is believed that, in making single determinations of blood sugar for purposes of clinical diagnosis, the time of the menstrual period should, in so far as possible, be avoided. This conclusion is borne out by a limited number (approximately fifty) of additional observations on subjects not to be rated as strictly normal physically.

Loss of Bases in Diuresis.—It has been demonstrated by Hendrix and Calvin that in diuresis due to sodium nitrate, sodium chlorid, sodium sulphate and urea, there is a loss of base through the kidney over and above that lost normally. Together with this loss of base in the urine, there is a marked fall in the alkali reserve. The loss of base is believed to be due to a failure of reabsorption from the tubules, since the tubules are flooded and overtaxed, and cannot be supposed to function as efficiently as normally in the retention of the basic ions. The effect of sodium nitrate diuresis on the alkali reserve is transient, passing off quickly, while the effect of sodium chlorid diuresis is more prolonged.

Physiologic Ontogeny.—Observations made by Cohn and Murray on tissue cultures of heart muscle from chicken embryos indicate that, in general, the growth rate of the individual cells decreases with age. The negative acceleration of growth is greatest at the beginning of life as in the intact embryo. The latent period is greatest near the end of the incubation period, thus demonstrating that the factors determining the initiation of growth and those determining the extent of growth are not similar.

Rate of Heart Beat During Development.—This study by Cohn has made possible the presentation of a curve which shows distinctly that changes take place in the rate of the *heart beat during the development of the chick embryo.*

Etiology of Jagziekte.—Jagziektc is a specific chronic catarrhal pneumonia of sheep which is peculiar to South Africa. The name is derived from the Dutch *Jagt*, to drive, and *ziekte*, a sickness, the combination of which is intended to indicate that the initial symptoms become first noticeable when the animals are driven for some distance. It is thought to be contagious and causes severe economic losses. An interesting feature of the disease consists of an extensive overgrowth of the pulmonary epithelium, but it is not known whether this proliferation constitutes the primary lesion nor has its tumor-like structure been studied. Cowdry describes the primary changes.

Immunologic Study of Pneumococcus.—Avery and Morgan assert that the isolated carbohydrate of pneumococcus is nonantigenic in the sense of stimulating antibody formation. The isolated protein of pneumococcus is antigenic: it induces the formation of antibodies which react with the nucleoprotein fraction of organisms of homologous and heterologous types. The antiprotein serums do not agglutinate type-specific strains of pneumococcus, or react with the carbohydrate derived from them.

Antigenic Properties of Pneumococcus.—Avery and Neill state that intact pneumococci, possessing specific antigenic powers unimpaired by cultural or other procedures, give rise to agglutinins for organisms of the homologous type and to precipitins for the type-specific carbohydrate derived from them. Solutions of pneumococci free of all formed elements, but containing the carbohydrate and protein of the original cell, fail to stimulate the formation of type-specific antibodies. Serums prepared in this manner do not react with the carbohydrate constituent of the cell and do not agglutinate organisms of the homologous type. The loss of this antigenic function is related to changes incurred during dissolution of the bacterial cell. Solutions of the cellular substances of pneumococcus, although lacking the specific antigen of the whole cell, induce the formation of antibodies reactive with pneumococcus protein regardless of the type from which the latter is derived.

Immunologic Relationship of Pneumococcus.—The general immunologic significance of the intact pneumococcus cell and of its protein and carbohydrate components are discussed by *Avery and Heidelberger.*

Compensatory Hypertrophy of Thymus.—Evidence of uncomplicated hypertrophy of the thymus was obtained by Gottesman and Jaffe by removing one lobe and studying the enlargement of the remaining lobe. The results clearly indicate that such hypertrophy takes place in young animals. They emphasize the functional importance of this gland before puberty, since the compensatory enlargement does not take place after puberty. The results further indicate that with the onset of involution there is a marked or almost total decline in the function of the gland, in spite of the fact that anatomically the thymus may persist to old age. With the appearance of a stimulus for regeneration, as suprarenalectomy, the involuted gland takes on functional activity.

Journal of Nervous and Mental Diseases, New York

62: 225-336 (Sept.) 1925

Pathology of Dementia Praecox. N. D. C. Lewis, Washington, D. C. —p. 225.
*Double Effect of Calcium on Vegetative Nervous System. E. Barath, Budapest, Hungary.—p. 261.
*Cerebrospinal Fluid in General System and Metabolic Diseases as in Nephritis, Diabetes, etc. B. J. Alpers, Philadelphia.—p. 265.
Case of Cervicomedullary Tumor. J. Favill, D. E. Faxon and D. A. Palmer, Chicago.—p. 279.

Effect of Calcium on Vegetative Nervous System.—Barath maintains that in contradiction to the results of experiments made on surviving organs, the effect of calcium on men is manifested in a double reaction: in the initial period there are strongly expressed symptoms of vagus excitement of short duration and these are followed by a less strongly expressed period of sympathetic excitement with longer duration increase of the blood sugar and blood pressure, sometimes epinephrin mydriasis, etc. The effect of calcium is an amphotrop effect, that is to say, an effect which manifests itself on both parts of the vegetative nervous system.

Cerebrospinal Fluid in Systemic and Metabolic Diseases.—*A series of cerebrospinal fluids collected from the literature* and from hospital reports form the basis of Alpers' report. In diabetes mellitus, sixty-five spinal fluids were studied. In 60 per cent. of the cases the cell content was normal, and in 40 per cent. either moderately or definitely increased. Most of the cases with an increased cell count, however, showed the presence of some complication, such as gangrene, tuberculosis, or pneumonia. The spinal fluid pressure was normal, and the protein content showed a slight increase in about 45 per cent. of the cases. *Forty-one spinal fluids from cases* of chronic nephritis without the presence of a uremia showed clear and colorless fluids in all cases. Most of these were cases of nephritis with hypertension. In 83 per cent. the cell count was normal, and in 17 per cent. it was definitely increased. In 30 per cent. a slight to a moderate increase in the protein content was recorded. The Wassermann, when done, was always negative. In uremia the spinal fluid changes are different from those in nephritis. In "pure" uremia the pressure is always elevated, the urea content is increased. In cases of "associated" or "secondary" uremia the amount and pressure of the *spinal fluid are definitely* increased, the cells are usually normal but may be increased, the chlorids are increased in amount, the albumen content is qualitatively normal and the urea content is elevated. Cases with a content of over 0.2 per cent. are rapidly fatal, and those with a content of from 0.1 to 0.2 per cent. show a severe retention and a fatal termination if not cared for. In jaundice the spinal fluid is occasionally yellow, probably in from 15 to 20 per cent. of the cases. Sixty-nine cases of gastro-enteritis showed no abnormalities in the spinal fluids. Cases of chronic endocarditis, chronic myocarditis, and subacute bacterial endocarditis showed no deviation from the normal in their spinal fluid findings. In twenty-one cases of lobar pneumonia without signs of a meningismus an increase in the cell count was noted in 13 per cent. of the cases. In eighteen cases of bronchopneumonia the cells increased in 33 per cent. of the cases. No other significant findings were noted. Twenty-five cases of pneumonia with signs of meningismus showed normal spinal fluid findings. In typhoid fever a hyperglycorrhachia had been reported, and also a decrease in chlorids. Fifty per cent. of the cases of pulmonary tuberculosis showed an increased cell content, but no other findings. Endocrine disorders were studied but no conclusions could be drawn from the few cases available for study.

Etiology of Epileptiform Convulsions.—A series of 210 cases of epileptiform convulsions has been studied by Nielsen with a view of determining the etiologic factors. All points not comparable with recognized normal standards have been carefully compared with a series of 200 consecutive nonneurotic cases. No age is exempt. The curve of age incidence of the first convulsion shows three peaks, 20, from 30 to 35 and 50. The curve of symptomatic convulsion cases runs remarkably parallel to those of the idiopathic types. The male sex predominates in the proportion of sixty to forty in idiopathic cases and sixty-six to thirty-four in the symptomatic cases The latter is apparently due to the greater incidence of arteriosclerosis, toxemias, etc, in males. Constipation is a marked predisposing as well as exciting factor or else epilepsy produces constipation. The basal metabolism in this short series is somewhat lower in epileptics than normal. Migraine headaches coexist with epilepsy in about 12 per cent. of cases. The finding of a small sella, thickened posterior clinoid processes or both occurs in about 39 per cent. of the cases *of idiopathic convulsions and in about 28 per cent.* of symptomatic convulsion cases Blood sugar, blood pressure, hemoglobin content and differential blood count do not vary from the normal cases in epileptiform convulsions. Since the symptomatic cases show an age curve similar to that of the idiopathics hereditary taint, constipation, sella turcica pathology and possibly lowered basal metabolism, nearly as great as that shown by the idiopathics, it would appear that the symptomatics are potential epileptics "waiting for" an exciting cause If this be the case, the "cause" of a symptomatic convulsion is merely the exciting factor in the case.

Epilepsy: Type of Heredofamilial Degeneration.—The contention is advanced by Alford that a great deal may be learned about epilepsy by considering it in relation to other nervous affections that seem to be of similar nature. The affections most similar to epilepsy appear to be the heredofamilial *degenerations or abiotrophies, examples of which are the* muscular atrophies and dystrophies, paralysis agitans, Huntington's chorea, progressive cerebral diplegia, myoclonus, dementia praecox, and other conditions. In these conditions the pathologic process is a degeneration of cells and fibers which arises from inborn weakness. In each condition a characteristic set of cells and fibers is involved. In epilepsy the convulsions are assumed to be representative of a type of extrapyramidal motor involvement and to be in series with tremor, chorea, athetosis and incoordination which are types of extrapyramidal disturbance found in others of the group of abiotrophies. The mental aspects of epilepsy are similarly considered to be comparable to the mental disturbances found *in Huntington's chorea, cerebral diplegia and dementia* praecox. The fundamental causative influence is heredity, although other processes may act in conjunction with heredity as it is now understood.

Treatment of Asthma.—Brown summarizes the treatment of asthma thus: Consider the psychic aspects of the case; remove sources of peripheral irritation, especially in the upper air passages; employ chest development exercises, especially in the young asthmatic, whose respiratory intake is usually poor; desensitize where practicable; restore the balance in favor of the sympathetic, and attend to the general hygiene.

Carcinoma of Ovary in Child.—Potter's patient, aged 8, had complained for four days of pain in the lower abdomen; it was constant and severe, increasing very much during defecation. For two days the lower abdomen had been seen to be swollen. A tumor was visible rising above the pubes to just below the umbilicus. It was firm to the touch and slightly tender. On rectal examination a mass was palpable in the pouch of Douglas. A tentative diagnosis of appendix abscess was made. At operation, a solid tumor was found, growing from the left ovary but extending to and enveloping the right. It was all encapsulated except the right extremity, which was fungating and becoming adherent to coils of small intestine. The tumor, with both ovaries and tubes, was removed. No other focus of growth was seen. On microscopic examination the tumor proved to be a spheroidal cell carcinoma. Twelve days after the operation enlarged glands appeared in the right groin and two days later in the left groin. A month later the child was readmitted with a tumor similar to the original one, and nodules, one of which was fungating through the wound in the abdominal wall. She died ten days later. Permission could not be obtained for a postmortem examination.

Adhatoda Vasica.—Chemical analysis of *Adhatoda vasica* shows the presence of two active principles: (*a*) an alkaloid, vasicine, and (*b*) traces of a volatile principle of the nature of an essential oil. Vasicine has no marked action on the alimentary canal or on the circulation. It produces slight but persistent bronchodilation in experimental animals and this effect is considerably increased after administration of atropin. Clinically, a fluid extract prepared from the leaves has well marked expectorant properties and relieves bronchial spasm.

Mercurochrome-220 in Treatment of Malaria.—Kingsbury and Kanagarayer report a case of benign tertian malaria in which a total of 0.3 gm. of mercurochrome-220 soluble was given over three days. On the withdrawal of acetylsalicylic acid and three days after the last mercurochrome injection a typical rigor occurred, with a temperature of 102.9 F. A malignant tertian case received a similar quantity of mercurochrome, and fever recurred two days after the last injection. The dye appeared to have little effect on the number of malaria parasites in the peripheral blood and caused no modification in their staining properties. In neither case did albuminuria develop. Kingsbury and Kanagarayer consider that the action of mercurochrome on malaria parasites is practically negligible, and that in view of the unpleasant sequelae which result from its exhibition, it should not be given in cases of malarial fevers.

Excision of Pineal Body Under Intra-Arterial Anesthesia.—Twenty c.c. of a 2 per cent. solution of gum acacia containing one-quarter grain cocain hydrochlorid and 5 minims of epinephrin hydrochlorid (1:1,000) was slowly injected into the lumen of the collapsed artery. After a lapse of five minutes the head and face were completely anesthetic. No signs of shock were noticed either during or after the injection.

Pathognomonic Sign of Retrocecal Appendicitis.—The sign referred to by Tresidder was the position of lying flat on the face and abdomen, thus allowing the cecum to fall away from the inflamed appendix and giving relief from pain.

Length of Muscle and Heat Production.—Experiments are described by Hill by which the relation between heat production and length of muscle was determined over a range of lengths from about 50 to 140 per cent. of that of the resting unloaded muscle. The same effects were found for all temperatures and for all durations of stimulus.

Heat Produced by Muscle Contraction.—Fenn's result has been confirmed by Hartree that when a muscle shortens, doing work, and provided that the weight lifted is held up and does not bear on the muscle during relaxation, the energy liberated in the form of heat is constant, that is, it is the same as the heat liberated in an isometric contraction, and independent of the load. In such a contraction, therefore, the muscle supplies extra energy equal to the work done.

Blood Coagulation.—Because the blood plasma of the domestic fowl collected in paraffined tubes and centrifugalized in the cold contains all the material essential for clotting, it is concluded by Pickering and Reeves that blood coagulation can occur without the intervention of either thrombocytes or tissue juices. Lowering the surface tension of this plasma increases its tendency to clot, but does not provoke immediate coagulation.

Action of Insulin.—Quantitative chemical and microscopic evidence is given by Secker in support of the view that the mechanism of insulin is to increase the permeability of the cell membrane. Guanidin resembles insulin in its action of increasing permeability. The presence of calcium is essential for this action of guanidin.

Sensitivity to Insulin.—Bainbridge fed rats and mice on a diet containing protein, salts and vitamins, from which carbohydrate was omitted, the necessary calory value being maintained by an increased amount of fat. Such animals developed a high degree of resistance to insulin. Certain experiments make it appear probable that an increased amount of carbohydrate and complete absence of fat in the diet render the animals still more sensitive to insulin than they would be on a complete diet, but this cannot be considered to be definitely proved. The variations in sensivity are not due to deficiencies in the amount of vitamin A present. The evidence as to the importance of the thyroid glands is inconclusive.

Electrical Resistance of Skin.—It is shown by Avelling and McDowall that in the cat a fall of the electrical resistance of the skin is associated with the constriction of vessels and that a rise is associated with a dilatation. Reasons are put forward why the fall of skin resistance which occurs on sensory stimulation may be considered to be due to similar vasoconstriction. The resistance of the skin may apparently be used as an indication of its vascularity.

Gongylonema as Cause of Cancer.—The peculiar topographic distribution of cancer in Romagna, the prevalence of the disease in the esophagus and in the cardiac portion of the stomach, the constant presence of cockroaches, meal beetles and cellar beetles—all fosterers of the larval stages of *Gongylonema neoplasticum* in the houses where cancer cases had occurred, led Sambon to wonder whether *Gongylonema* might not be a factor in the causation of certain neoplasms affecting the upper portion of the alimentary tract of man, as is well known to be the case in rats infested by this spiruroid worm.

Yatren in Treatment of Amebic Dysentery; Results of Stovarsol in Certain Cases. P. H. Manson-Bahr and R. M. Morris.—p. 544.

Experimental Treatment of Implanted Malignant Tumors.—The tumors employed by Lumsden in this study were the mouse carcinoma (M. 63 of the Imperial Cancer Research Laboratory) and Jensen's rat sarcoma. In most cases the sarcoma was used because it was found that while M. 63 is very satisfactory for in vitro work, it is less suitable for experiments in vivo. It appears that an appropriate antiserum kills cancer or sarcoma cells in vitro, rapidly and invariably. It is much less toxic to the normal tissues than to the malignant cells. Pieces of cancer tissue kept in antiserum for from three to six days at 37 C. do not thereafter produce a progressive tumor when inoculated into the living animal. Jensen's rat sarcoma of the foot can be caused to disappear by repeated injections of antiserum into and round the tumor, along with temporary stoppage of circulation in the foot. After such removal of a tumor the rat becomes immune, so that a subsequent inoculation of Jensen's rat sarcoma into the other foot or into the axilla does not hold. When an implanted tumor is growing on each foot, removal of one of these by means of antiserum and constriction is, in a large proportion of cases, followed by absorption of the tumor in the other untreated foot. It is suggested that during absorption of the tumor after treatment with antiserum and constriction, the products absorbed from the attenuated or dying cells evoke a general active immunity which completes the cure and prevents subsequent grafts from holding. Such an antiserum might in this way prevent recurrence of a tumor after incomplete surgical removal.

Chronic Nephritis with Parathyroid Syndrome.—Box and de Wesselow report the case of a patient presenting definite evidence of chronic azotemic nephritis, and in addition an increased basal metabolic rate, a possible increase of sugar tolerance, and a recurrent laryngeal paralysis. On the chemical findings the most striking is the abnormally high calcium content of the serum. At one time it reached 20 mg. This extraordinary variation of what is usually one of the most constant constituents of the blood naturally suggests an involvement of the parathyroids. Such an involvement would be of the nature of a hyperplasia, since parathyroidectomy leads to a fall in the serum calcium. There appears, therefore, to be good evidence of a connection between chronic renal disease and parathyroid hyperplasia, and of the possibility of a mobilization of calcium salts in the condition.

*Luminal Poisoning. H. Carlill.—p. 596.
*Renal Glycosuria with Ketonuria. J. Patterson.—p. 596.

Immunity to Toxin of Scarlet Fever Streptococcus.—Henry and Lewis found that the serum of persons who are sensitive to small doses of toxin contain little or no antitoxin. On the other hand, the serum of resistant persons contains a measurable quantity of antitoxin, amounting to as much as 500 units. That this amount is considerable may be judged from the fact that the best of a series of horse antitoxic serums titrated against 20 units of toxin have given a unitage of about 800 on the same scale.

Heart Disease in England and Wales.—From the data that have been investigated by Young he concludes: (1) The mortality from heart disease in the counties of England and Wales shows quite definitely a tendency to a special distribution in which the higher death rates are found in the counties toward the west. (2) The geographic distribution of the relative mortalities in the periods examined is very different from that described by Haviland as occurring in data for an earlier epoch, and the explanation offered by him—namely, that the excessive incidence is found in counties that are distant from the sea and sheltered by their physical surroundings from the sea winds, cannot be held to account for the distribution of the fluctuations in incidence in the present data. A definite association exists in the counties between the distribution of mortality from organic heart disease and heart diseases in the aggregate and the mortality from acute rheumatism. The relative incidence of acute rheumatism appears to be the essential factor that determines the incidence of heart disease, although other factors, possibly mainly environmental, may have some influence on the rate of mortality in different districts.

Luminal Poisoning.—In the case cited by Carlill luminal and potassium bromid in small doses were prescribed but, inadvertently, 10 grains of the former and 50 grains of the latter were administered daily for twelve days. On the twelfth day, she became stuporous and had a recurrence of double incontinence. The pupils were much contracted and lost their reaction to light. At times there was a divergent squint. The pulse rate was increased. The cerebrospinal fluid was under normal pressure. The urine contained no hematoporphyrin. After stimulation and a long delay she feebly obeyed certain instructions. Energetic treatment was employed in the form of strychnin, hot coffee by mouth and rectum, oxygen and faradism. The luminal and bromid were canceled. For a few days the periods of mental alertness increased in length but on each occasion she relapsed rapidly into stupor. Her conversation showed extreme confusion of thought. The tendon and superficial reflexes were unaffected throughout. The patient eventually recovered.

Renal Glycosuria with Ketonuria.—In Patterson's case the urinary examination was apparently contradictory to the findings based on blood analysis. The most striking feature was the continuous excretion of acetone bodies, a fact not merely based on a positive reaction but confirmed by more conclusive tests. The withdrawal of carbohydrate in the form of potatoes from the diet, or on the other hand, the addition of glucose, had no appreciable effect. The appearance of a ketonuria in these circumstances is evidently contrary to the present-day theories as to the relationship between carbohydrate and fat metabolism, unless it be assumed that in addition to a very low threshold for sugar the patient had also a lowered threshold for acetone. Unfortunately, it was not found possible to carry the investigation further in order to establish whether this were so or not, but since the abnormality cannot be accounted for on the basis of lack of carbohydrate utilization, it seems feasible to suggest that its cause is a parallel one to that responsible for the abnormality of the accompanying sugar excretion.

*Treatment of Acute Rheumatism and Its Allies J. Wishart —p 225

Middle Ear Infection.—In every case of chronic disease in which it is suspected that septic absorption from some local source is a factor, Watson-Williams insists that the ears be examined. In every case of chronic otorrhea, when the matter of operative treatment is under consideration, regard should be had, not only to the local conditions, but also to the actual or possible results on the general health of septic absorption.

Dosage of Insulin.—Cammidge says that if the best results are to be obtained from the insulin treatment of diabetes, once it has been decided on, the dose is a matter of great importance, for too little will not stay the progress of the disease, whereas too much may have disastrous consequences. Many factors enter into the determination of the optimum dose, and since they are never exactly the same in any two instances, each case is a law unto itself; but if the conditions existing are accurately ascertained for each patient, it is possible to secure very satisfactory results with comparatively small doses, even in seemingly severe cases, and, further, a reduction is often possible, as influences interfering with the full physiologic effect of the insulin administered are eliminated or minimized by suitable diet and treatment.

Colon Bacillus Infections.—Rooke is of the opinion that colon bacillus infection is extremely prevalent, and is the cause of a great deal of chronic ill health. The stage of invasion is usually ushered in by an acute febrile illness, but it may be insidious in its onset. The condition tends to become chronic. Relapses or reinfections are the rule rather than the exception. The majority of cases are associated with colitis. Gross lesions, such as appendicitis, cholecystitis and renal infections, are extremely common. Toxic manifestations, such as irregular heart action, mental depression, and derangement of the thyroid, frequently occur. Treatment must be directed toward (1) improving the condition of the intestine, and (2) increasing the patient's resistance. In order to prevent the disease from becoming chronic, treatment must continue for a long period after all signs and symptoms have cleared. It is as necessary for the *B. coli* infected patient to have the urine examined from time to time as it is for the syphilitic to have repeated Wassermann tests.

Fate of Disused Portions of Intestine.—Five years ago Stretton performed a complete short-circuiting operation on a woman, aged 31. He divided the ileum 12 inches from the ileocecal valve, closed the distal end, and planted the proximal end to the sigmoid flexure of the colon. He divided the colon above the anastomosis and closed both the cut ends. The patient made a good recovery and was able to perform her household duties. When he saw her again in 1925, she was suffering from acute distention of the abdomen. At operation it was found that the distention was caused by an enormous dilatation of the disused portion of colon. Stretton asserts that this is the only case of its kind on record. Usually the disused portion of bowel remains quiescent, and gives rise to no trouble.

Treatment of Tonsillitis.—Wishart treats each attack of tonsillitis as if it were premonitory to an attack of rheumatic fever. With the aid of an atomizer or throat brush he applies to the tonsils, during gentle expirations, a paint consisting of one part of tincture of iodin to seven parts of anesthetic ether, until the tonsils become iodin colored and dry. It may be found necessary to repeat the application every third day.

The Spirochete Which Causes Mumps. Y. Kermorgant.—p 565.
*Resistance of the Galeria Bee-Moth to Tuberculosis Metalnikoff.—p 629.
*Rapid Preventive Treatment of Rabies. A. Hempt.—p. 632.

Natural Immunity of the Galeria Against Tuberculosis.—Metalnikoff found that the caterpillars of *Galeria melonclla* were refractory to enormous doses of tubercle bacilli, even during their chrysalis phase. The same resistance to tubercle bacillus infection was manifest in the chrysalis and in the moth stage. Microscopic examination of blood and sections revealed that the natural immunity of the galeria to tuberculosis was due exclusively to phagocytosis. The same results were obtained with human, bovine and avian tubercle bacilli.

Rapid Ether Method for Antirabies Treatment.—Hempt asserts that by inoculations of fixed virus, treated with ether, the subject can be immunized against rabies in three or four days in mild cases; in five or six days in grave cases. He used an emulsion of ether-treated virus diluted with saline. In adults 1 or 2 gm. of the nerve substance were injected in mild cases; 3 gm. when the conditions were grave, and 4 gm in the very grave. In mild cases, the treatment started by injections of brain emulsion. For children, the dose of vaccine corresponded to their age and weight. The injections were given twice a day. Of 6,000 persons given this treatment during the last three years, only two died during the treatment and one in the first fifteen days' interval.

Primary Syphiloma in Urethra. Jamain —p. 591.
Gonococcus Infection by the Mouth. Carle —p. 593.

The Colloidal Benzoin Reaction.—The results of the test harmonized with those of the Wassermann test in 86.9 per cent. of Starobinsky's 516 cases. The benzoin test seemed to be the more sensitive of the two in patients with latent or visceral syphilis. In eleven cases of suspected syphilis, the test was positive while the Wassermann was negative. The pronounced specific character and easy reading of the results render the benzoin test, he says, at least valuable in controlling and completing the complement fixation reaction if not capable of replacing it entirely.

*Glycemia and Cholesterolemia. Landau et al.—p. 143.
Lactic Acid in Blood of Diabetics. Collazo and Lewicki.—p. 153.

Cholesterolemia in Diabetics with Arteritis Obliterans.—Labbé and Heitz' conclusions are based on nineteen observations. The exaggerated amount of cholesterol in the blood of these patients does not seem to be connected with liver disturbances, albuminuria, the arterial pressure or syphilitic lesions. Cholesterolemia is more pronounced in grave cases with acidosis, or with deficient permeability of the arteries, coinciding with reduction or abolition of the oscillometer findings. The cholesterol content is particularly high in diabetics affected simultaneously with aortitis and arteritis. Arterial obliteration in diabetes is due to localization of cholesterol in the tunica intima. While sodium citrate did not display any action on the cholesterol content, insulin markedly reduced its amount.

The Relations Between the Sugar and the Cholesterol Content of the Blood.—Landau and his co-workers' investigation in sixteen persons indicated that food rich in cholesterol and free from carbohydrates increased the content of sugar and cholesterol in the blood. Epinephrin injection or ingestion of a large dose of sugar, raising the glycemia curve, reduced the cholesterolemia. Hunger increased the cholesterol content of the blood within the first thirty-six hours, while lowering the glycemia.

39: 947-974 (Aug. 29) 1925

*Multiple Sclerosis: Early Diagnosis. R. A. Marquézy.—p. 953.
Idem: Ophthalmologic Signs. Lagrange and Marquézy.—p. 957.
Idem: Etiology. R. A. Marquézy.—p. 960.

Early Diagnosis of Multiple Sclerosis.—Marquézy has observed transient difficulty in sewing or in writing, or chilliness of one foot or paresthesia as the first symptom of sclerosis in patches. One patient had these attacks in an extreme form nearly daily for seven months; then there was an almost complete respite for two years. Other patients complained of progressive or sudden reduction of vision, but it was always transitory. Others of heaviness of the legs, or vertigo, the room turning around the subject, but no nausea. Sudden movements of the head, fatigue or emotional stress may bring on these symptoms. Urinary disturbances were noted early only in about a third of his patients, and never as a very early symptom. The repetition, the intensity and the grouping of these mild symptoms are characteristic. He has also had exceptional cases that began with acute hemiplegia, subsiding in a few weeks. The age, 18 to 30, is significant, as also the wavelike character of the disturbances. The colloidal benzoin test was positive with spinal fluid in 63 per cent. of twenty-seven cases; the Wassermann negative.

Method of Preparation of Silica Agar for Bacterial Cultures.—Souleyre describes the technic for rapid preparation of a silica gel by elimination of the silicate base under the form of insoluble potassium bitartrate.

Glucose and Phosphorus of Blood in Vitro.—Bierry and Moquet's experiments indicated a continuous decrease of glucose in blood kept in the thermostat. The phenomenon, especially marked in the second half hour, was accompanied also by diminution of the inorganic phosphorus. The disappearance of the glucose as well as of the phosphorus was accelerated when insulin was added to the blood.

Complications with Subcutaneous Injections of Human Serum.—Debré and Bonnet have injected over 1,100 children with serum against measles, whooping cough and mumps—a total of 7 liters of human serum. Complications occurred in about 2 or 3 per cent.—a local redness with edema appearing within the first hours and persisting one or two days. This was associated sometimes with fever and general malaise. The phenomena seem to be analogous to those from reinjection of horse serum in already sensitized subjects.

Vaccination by the Skin Against Anthrax.—Brocq-Rousseu and Urbain conclude from their experiments on eleven guinea-pigs that skin vaccination against anthrax confers immunity including all the organs. The animals proved resistant to several times the fatal dose of the virus, injected into the brain directly or through the orbit.

Action of Spartein on Heart and Arterial Pressure in Dogs.—In the Merciers' research on dogs, spartein sulphate increased the amplitude of the heart contractions without reducing the force of the myocardium. It retarded the cardiac rhythm to normal, but did not induce a permanent reduction of the arterial pressure.

Effect of Trinitrin and Amyl Nitrite on Venous Tension.—Inhalation of amyl nitrite caused in all five persons lowering of the venous tension, preceded in one case by brief hypertension. The action of trinitrin was analogous in seven cases; preceded by hypertension in three. Payan and Giraud ascribe the phenomenon to paresis of the sympathetic, with consecutive vasodilation; this was sometimes preceded by a short phase of vasoconstriction.

Advantage of Treating Serums from Convalescents with Formaldehyd.—Costa and Boyer add one part of 40 per cent. solution of formaldehyd to 2,000 parts of serum. With this method, complement fixation tests are unnecessary, since the syphilis spirochetes are destroyed by formaldehyd within a few hours. The immunizing action of the serum does not seem to be weakened, and the subcutaneous injection does not cause pain.

Influence of Ox Bile on Paratyphoid Infection in Rats.—Inoculation of the peritoneum with the paratyphoid B bacillus was fatal in rats, with ox gall injected simultaneously or three hours afterward. Further experiments with cultures on ordinary agar, or agar treated with bile, showed that the latter does not enhance the virulence of the paratyphoid bacillus, but it seems to reduce the resistance of the organism to the infection.

Uremia and Albuminuria in Scarlet Fever.—Retention of urea (from 0.05 to 0.2 per cent.) in the blood occurred in sixty-three of Ciuca and Nadejde's 108 patients with benign scarlet fever. In thirty-nine, neither albumin nor renal elements were present in the urine. In nineteen cases of nephritis with edema, complicating a mild form of scarlet fever, from 0.039 to 0.4 per cent. of urea was found in the blood. No albumin or renal elements were found in the urine of one patient. In twenty-one cases of grave scarlet fever, uremia existed in 97 per cent. while albuminuria appeared only in sixteen. In four fatal cases the amount of urea in the blood was 0.2 per cent.; but there were no pathologic elements in the urine. Evidently the diet in scarlet fever should be based on the dosage of urea in the blood.

Journal de Chirurgie, Paris

26: 1-128 (July) 1925

*Surgery for Excessive Muscular Tonus. P. Wertheimer.—p. 1.
*Access to External Carotid. L. Hartglas.—p. 11.

Sympathetic Ramisection in Treatment of Rigidity and Contracture of Muscles.—Wertheimer reviews the history of attempts to cure pathologic rigidity of muscles by operative means, especially section of the rami communicantes for excessive plastic tonus. The research at Lyons (Leriche and Wertheimer) and the work of Hunter and Royle have demonstrated that this is not a dangerous operation, and that it has a solid physiologic basis, and opens a new field of surgery.

Ligation of External Carotid.—Hartglas calls attention to the internal jugular vein as a reliable guide to the site of the bifurcation of the carotid. This vein is readily palpated, and when drawn forward and inward it allows free access to a comparatively long extent of the carotid artery, unless enlarged glands obstruct the way.

Journal de Médecine de Lyon

6: 453-484 (Aug. 20) 1925

Galvanic Functional Tests of the Internal Ear. L. Bard.—p. 453.
Rupture of Vessels in Soft Palate. J. Garel and A. Gignoux.—p. 461.

Tonsillectomy in Rheumatism. R. Bertoin.—p. 471.
Radiotherapy in Otorhinolaryngology. H. Proby.—p. 475.

The Vegetative Nervous System in Children with Adenoids.—Rebattu and Paufique examined ninety-nine children with adenoid vegetations. The arterial tension was decreased in 70 per cent.; the oculocardiac reflex exaggerated in 63 per cent.; diminished in 4 per cent. and normal in 23 per cent. Epinephrin injections only exceptionally increased the arterial tension, but accelerated the pulse in 50 per cent. of the patients. Pilocarpin injections exaggerated the oculocardiac reflex in 50 per cent. of the children. Evidently subjects with adenoid vegetations present a disturbed vegetative system. chiefly characterized by irritability of the vagus. This may explain the accompanying asthma in several of the children.

*Béranger's Cataract Operation in 1757. C. Fromaget.—p. 1354.
*Daviel's Operation for Cataract in 1745. Aubaret.—p. 1358.

Herpes Zoster of the Eye.—Sédan applied autohemotherapy in two cases with unilateral hypotension from zoster ophthalmicus. Eight subscapular injections were given at three day intervals The first injection was of 5 c.c.; the second and third, 10 c.c.; the fourth, 15; the fifth, 20 c.c.; the last three from 30 to 35 c.c. of own blood. Rise of the intra-ocular tension and improvement of visual acuity were manifest after the fifth injection. Under this treatment the pain rapidly subsided and the zoster lesions on the cornea retrogressed. Each injection of the blood raised the tension for twenty-six to thirty hours. Vision was 8:10 to 9:10 three months later.

The Pioneers in Cataract Operations.—This issue of the *Marseille-médical* is devoted to ophthalmology in honor of the hundred and eightieth anniversary of the extraction of the opaque crystalline lens by Daviel in 1745. He came to Marseille in 1721 to help fight the plague, and was made chief surgeon to the hospital. Béranger, who introduced twelve years later the method of extraction of the cataract in the capsule, practiced at Bordeaux. A letter from Daviel describing his work is reproduced.

*Visualization of the Gallbladder. G. Sabatini and E. Milani.—p. 1160.
Dropsical Appendix and Gallbladder. Petrescu and Lazarescu.—p. 1161.

Association of Spirochetes in Chancroid.—Hudelo and Rabut noted coexistence of syphilitic infection in one of every seven in 173 patients with chancroid. They emphasize that association of Ducrey's bacillus with the spirochete of syphilis may not be detected for two months, since the incubation period of the latter is in certain cases prolonged, and a positive Wassermann reaction may not appear till late.

Occupational Tumor of Stenson's Duct.—Sénèque describes a gas tumor of Stenson's duct in a glass-blower employed for thirty-five years. The tumor completely disappeared under roentgen-ray treatment. Six exposures were given, to a total of about six hours. Ligature of Stenson's duct or avulsion of the auriculotemporal nerve should be tried only after irradiation has failed.

Treatment of Lacerated Semilunar Cartilage.—Bressot found injury of the semilunar cartilage in twelve cases out of thirty with trauma of the knee. The characteristic signs of the injury are recurring hydrarthrosis and pain inside the line between the articular cartilages. The lesion is usually an incomplete laceration of the internal cartilage. The operation of choice consists in removal of the entire fibrocartilage, after severing the internal lateral ligament. A cast is then applied for fifteen days. Three patients out of five, observed from four months to four years, recovered the normal use of the knee. The two with only partial meniscectomy were much improved but not quite cured.

Visualizing of the Gallbladder by Bromids.—Sabatini and Milani obtained a distinct picture of the gallbladder and gallstones after administration by the mouth of a single dose of 10-20 gm. of sodium bromid and strontium bromid, diluted in 100 or 150 gm. of water. Sometimes two doses of 10 gm. of the bromid were given at a four hour interval. Roentgenograms were taken from five to twelve hours afterward. The gallbladders were visible in 60 per cent. of healthy persons, and in over 80 per cent. of those with diseased gallbladders. The authors describe the details of the method, and reproduce instructive roentgenograms. They believe that the bromin is responsible for the success of the Graham-Cole intravenous tetrabromphenolphthalein technic. Ingestion by mouth of the bromids seems to answer equally well; bromin may be electively eliminated by the hepatic duct.

Cholecystostomy as Emergency Operation. J. Berger.—p. 1174.
Fascia of the Pelvis. N. Barbilian.—p. 1176.

"Inapparent" Typhus Infection: Rôle of Inapparent Infections in Epidemics.—Nicolle refers to experiments on guinea-pigs and rats showing an afebrile form of typhus, without clinical signs of the infection. The presence of inapparent typhus was confirmed by the virulence of the blood and organs, especially of the brain, from the animals. It represents an attenuated form of the disease while yet inducing immunity. The inapparent infection differs from latent infection, existing in bacteria carriers, which is a chronic condition. It is probable that such unrecognizable infection with whooping cough and measles may be responsible for certain epidemics.

Comparative Action of Raw and Boiled Meat.—Two dogs given meat, boiled for sixty minutes, eliminated 25 per cent. more urea; 52 per cent. more total nitrogen; 700 per cent. more chlorids and 20 per cent. more phosphorus than dogs fed with raw meat. The amount of eliminated water was also notably increased with boiled meat. Richet and Monceaux conclude that raw meat may be indicated in liver disease with a deficient protein metabolism and in diabetes insipidus, while boiled meat is preferable in nephritis with dropsy.

33: 1185-1200 (Sept. 5) 1925

*The Graham Test by the Mouth and Vein. Gosset and Loewy.—p. 1185.

Anterior Poliomyelitis of Syphilitic Origin. Fribourg-Blanc and Jausion.—p. 1190.
Protein Therapy in Gastric and Duodenal Ulcers. Oury.—p. 1192.

Cholecystography.—Gosset and Loewy discuss the results of the Graham method for visualization of the gallbladder by intravenous injections of sodium tetrabromphenolphthalein in eighteen cases, and by sodium tetra-iodophenolphthalein, intravenously, in forty-eight cases, and by the mouth in twelve. With the substances ingested, the roentgen-ray picture of a normal gallbladder was hardly visible, while it was distinct in cholecystitis with calculi. The best results were obtained with tetra-iodophenolphthalein by the vein. While slight lesions of the gallbladder cannot be detected at the present time, an exact diagnosis with the Graham-Cole test may be counted on, they say, in an average of 85 per cent. of all other cases.

Surgical Forms of Thyroid Tuberculosis. P. Aubriot.—p. 1207.
Irradiated Food in Treatment of Rickets. L. de Gennes.—p. 1210.

Nervous and Psychic Disturbances Coexisting with Skin Diseases.—Lortat-Jacob describes three cases of eczema, associated with obsessions and melancholia in women, aged from 25 to 55. In one instance recurring eczema was connected with epileptic seizures; in another, an eruption of an impetigo and lichen type accompanied general convulsions in a child, aged 4. The affections appeared to be congenital and were probably of syphilitic origin. The infection may involve the ectoderm controlling the development and functioning of the nervous system. Arsenicals are indicated in these cases.

3: 213-276 (Aug.) 1925

Passage of Secretion from the Pituitary into the Tuber-Infundibulum: Neurocrinia. R. Collin.—p. 213.
*Headache from Intracranial Hypotension. L. Cornil.—p. 229.
Embryology of the Pituitary in Birds. C. Pfeiffer.—p. 236.
Biologic Importance of the Lipoids of the Suprarenal Cortex. R. Porak.—p. 249.

Headache from Intracranial Hypotension.—Cornil does not refer to the transient headache after lumbar puncture nor to the hypotension from local sclerosis preventing production of cerebrospinal fluid. He describes three cases in which low blood pressure entailed such intracranial hypotension that severe and almost continuous headaches resulted. The low blood pressure in these cases was due to deficient suprarenal functioning, the result of a severe attack of influenza or the effect of mushroom poisoning or of deep radiotherapy of a fibroma. Other signs of suprarenal deficiency were prominent, some of the three women being confined to bed from the asthenia and pains in the lumbar and dorsal regions, spreading to the scapula and stomach. Two of the women displayed a slight tendency to pigmentation, and the headaches were of the meningitis type. In all the cases treatment with total extract of suprarenal banished the headaches at once; the general health improved more slowly. Suprarenal treatment, by raising the blood pressure, has a decidedly favorable action on this secondary headache from primary suprarenal insufficiency. Cornil adds that intraspinal injection of 1 c.c. of the suprarenal extract does not raise the pressure in these cases, but a rise in pressure by 30-40 per cent. is evident in four or five minutes after intramuscular injection. This confirms the assumption that arterial hypotension entails hypotension in the cerebrospinal fluid.

Pathologica, Genoa

17: 393-420 (Aug. 1) 1925

Changes of Leukemic Type in Blood of Rats with Tar Cancer. Balbi.—p. 407.
*Technic for Cultivation of Anaerobes. G. Vercellana.—p. 410.
Malformations of the Kidneys. G. Invernizzi.—p. 413.

Cultivation of Anaerobes.—Vercellana has modified Rockwell's pyrogallic acid method. Instead of pouring the acid on the cotton plugging the tube with the culture—which has certain disadvantages—he puts the pyrogallic acid in an Erlenmeyer jar below the culture. The agar is poured into a bottle to form a thin coating throughout the bottom of the bottle. This is inoculated with the micro-organism; the flask is then inverted, and the mouth is introduced into the mouth of the Erlenmeyer. The junction is made air-tight with shellac. He has cultivated in this way the bacillus of tetanus and of malignant edema, using in the jar 50 c.c. of a 10 per cent. solution of potassium hydrate and 5 gm. of pyrogallic acid, instead of Rockwell's mixture. Two test tubes can be used in the same way, shellacking the two mouths together. They can be separated by holding the shellac over a flame.

17: 421-448 (Aug. 15) 1925

Iron-Containing Cells in the Ovary. Puccinelli.—p. 433.
Medical Geography of Somalia. E. Corrado.—p. 438.
Basal Metabolism During Work and Fatigue. Caccuri Scipione.—p. 441.
*Salpingography. C. Vercesi.—p. 442.

Visualization of Fallopian Tubes.—Vercesi reproduces a roentgenogram taken after injection of iodized oil through the tubes. The flaring out of the shadow beyond the farther end of the tube is evidence of its permeability. He never witnessed any untoward by-effects from the use of this 40 per cent. suspension of iodin in a vegetable oil.

*Habitual Vomiting of Breast-Fed Infants. Cozzolino.—p. 449.
Nontuberculous Chronic Bronchopulmonary Affections in Young Children. G. Salvioli.—p. 476.

Habitual Vomiting in Breast-Fed Infants.—Cozzolino's experience confirms the prompt benefit from giving the infant one or two teaspoonfuls of a thick gruel or potato purée a few minutes before each suckling. He gives the details of fifteen cases in which this thick feeding promptly arrested the tendency to vomit. Only two required a little atropin in addition to conquer the gastric neurosis. He sometimes ordered moist heat to the stomach after nursing. The weight of the heavy gruel tends to break up the bad habit that has been acquired by the peristolic reflex. The success of this dietetic treatment is a touchstone to exclude a syphilitic or anaphylactic basis.

Policlinico, Rome

32: 1207-1237 (Aug. 31) 1925

*Fever in Secondary Syphilis. G. Antonelli.—p. 1207.
Iodized Oil in Roentgenology of the Pleura. P. Cignolini.—p. 1213.
"Aplasia of Suprahepatic Vein." Silvestri.—p. 1214. Reply. Bastai.—p. 1215.

Syphilis Simulating Malaria.—The young man presented fever every evening, beginning forty days after discovery of a primary chancre. A chill for a few minutes preceded the fever which reached 38 to 40 C. and terminated with a sweat as the night advanced. Headache accompanied the fever, and in time there were pains in the sternum and tibias. There was a four plus Wassermann reaction, and the spleen was not enlarged. After nearly four months of this pseudomalaria, the fever was arrested by a single injection of neoarsphenamin, after it had been returning for four months. Antonelli adds that women are more subject than men to essential secondary syphilitic fever. In his case there did not seem to be any manifestations of the syphilis outside of the fever, although skin and mucosa were repeatedly examined, but there was intense monocytosis, with relative lymphocytopenia and a tendency during the fever to nervous disturbances of a hystero-epileptiform nature such as had been observed years before on very rare occasions. He accepts this case as confirming Levaditi's theory of the distinction between the dermotropic and the neurotropic spirochetes.

32: 1273-1307 (Sept. 14) 1925

Hematogram in the New-Born in Health and Disease. Pollitzer.—p. 1273.
Cold Abscess of the Tongue. G. Fantozzi.—p. 1282.

Leukemia Following Trauma.—The man lost consciousness when hit in the chest by a log, but no fracture resulted and there was no vomiting or internal hemorrhage, only progressive weakness for three weeks, then bleeding from the gums. Blood changes indicating myeloid leukemia were followed by death, one month after the trauma. A recent second similar case of acute fatal leukemia after a trauma, and four that Martinelli has found on record raise the query whether the accident insurance companies were justified in refusing to accept a causal connection between the trauma and the acute fatal leukemia.

Connection Between Trauma and Cancer.—Speciale adds another case to the long list in which a sarcoma developed in the limb which had been injured not long before. The first symptoms of the malignant disease were noted a week after grave trauma of the ankle. There was no question of accident insurance in this case.

Rheumatic Nephritis.—In Vanni's case, the young man developed, twenty days after an infectious sore throat, severe pains in muscles and joints with hematuria and casts in the urine. Under salicylate treatment, the whole clinical picture promptly subsided, including the symptoms of nephritis.

41: 721-744 (Aug. 3) 1925

Peptic Ulcer in Meckel's Diverticulum. G. Pascale.—p. 721.
*Cancer in Upper Air Passages. S. Citelli.—p. 724.
*Oxaluria. F. Piccininni and E. Lombardi.—p. 726.
*Contamination Meningitis. G. de Toni.—p. 729.

Cancer in the Upper Air Passages.—Citelli has encountered forty-five cases of this kind, since 1918, in his ear, nose and throat clinic. Over half of them were under 50; the youngest was a boy of 12 with a carcinoma in the maxillary sinus. Citelli accepts the increasing prevalence of cancer, and especially that of the upper air passages, as an argument in favor of a parasitic origin. Metastasis was common and early.

Oxaluria.—Piccininni and Lombardi present data collected independently which demonstrate that a special strain of the colon bacillus sometimes acquires the property to produce oxalic acid. This strain continues to produce oxalic acid in the test tube, and also in persons free from oxaluria who ingest cultures of this strain; more or less oxalic acid then appears in their urine.

Meningitis from Contamination.—The meningococci in the infant's spinal fluid were concealed by the luxuriant growth of a saprophyte accidentally introduced, possibly by the physiologic solution sold for injection purposes.

Sarcoma in Child Kidney. R. Jemma.—p. 299.
Case of Familial Splenic Anemia. V. Tramontano.—p. 301.
Pruritus in Tabes. A. Oro.—p. 303.
*Milk Protein Therapy in Eczema. N. De Sanctis.—p. 307.
Spirochetes and Spirochetosis. M. Musella.—p. 308.

Parenteral Protein Therapy of Eczema in Infants.—De Sanctis has been treating eczema in thirty infants with intradermal injection of 2 c.c. of the same milk used repeated every second day or at longer intervals. Four of the infants were artificially fed, the others breast fed. Even after a single injection, in some of the children, the discharge dried up and no new lesions developed. Four injections usually completed the cure. He applied this "homologous galactotherapy" intradermally in order to utilize the defensive forces in the skin. He regards it as the simplest and most successful treatment for milk crust in infants, while it avoids all the inconveniences and dangers of local measures. One infant was in an extremely debilitated condition, the eczema involving the entire body, but it recovered completely with ten injections in thigh or buttocks of the mother's milk. No appreciable by-effects were observed except in one case in which there seemed to be an actual transient colloidoclastic shock.

Wounds and Disease of the Patella. D. Prat.—p. 348.
Case of Subacute Tetanus. J. C. Del Campo.—p. 357.
*Sexual Enlightenment of the Young. N. Leone Bloise.—p. 361.

Case of Alternating Regular Heart Beat.—Alvarez Mouliá gives eleven tracings of the alternating ventricle and auricle beat without extrasystoles. The wave in both the cardiogram and the jugular pulse showed the alternating auricle beat plainly.

Sexual Enlightenment of the Young.—Leone Bloise pleads for systematic handling of this subject by the parents, in the school and university, and by the family physician, as occasion presents. The father answering the questions of the little child in their walks begins this sexual enlightenment, and the teacher, the school physician, the senior medical students should assemble the fathers of the children to prepare them for this task, and continue it themselves later. He has been carrying on such work himself for eight years, and states that some of his earliest disciples recently expressed anew their perennial gratitude for his talks and guidance in sexual hygiene.

*Fatality from the Persisting Thymus. J. L. Morales.—p. 392.
*Nasal Pruritus in Meningitis. G. R. Lafora.—p. 398.

Remote Results of Plastic Operations.—Juaristi gives illustrations of three adults operated on in childhood, with deplorable ultimate results. In one young man, after an operation at the age of 3 for osteomyelitis of the maxilla, with extensive loss of substance, the ankylosis was almost complete. He removed the solid mass formed by the teeth that had interlocked as they grew. The dental prosthesis then provided was made with a bulging portion that tended to correct the extreme asymmetry of the lower part of the face. The case of extensive burn from waist to heel at the age of 8 had healed with cicatricial bands, and a large epithelioma in the dystrophia area has just been removed from the young woman.

Fatal Hypertrophy of the Thymus.—Morales' patient was a girl of 11 who had suddenly developed difficulty in swallowing, two months before, with attacks of suffocation especially at night, for which no cause could be discovered by auscultation, percussion or radioscopy, although there was slight inspiratory hissing, cyanosis, and tendency to syncope. Necropsy revealed a large thymus hidden behind the lungs, and he ascribes the symptoms to perverted functioning of the persisting thymus, as there were no signs of mechanical compression. The fatal suffocation occurred notwithstanding that the child was wearing a large O'Dwyer laryngeal tube. He endorses Marfan's plea for treatment as for syphilis in such cases.

Itching of the Nose an Early Sign of Meningitis.—Lafora ascribes this early symptom to irritation of the trigeminal nerve with incipient meningitis of any kind.

*Epinephrin Treatment of Glaucoma. G. de Andrade.—p. 287.
Sterilization of Instruments in Glycerol. E. Campos.—p. 291.

Epinephrin Treatment of Glaucoma.—De Andrade reviews the literature on this subject, and reports three cases of acute or subacute or simple glaucoma and a case of acute glaucoma in which he applied Hamburger's method of subconjunctival injection of epinephrin. The effect was uncertain and transient; at most it may serve to reenforce the miotic, or to tide along briefly until an operation is feasible. Any medical treatment, he says, has the disadvantage of misleading the patient to a false confidence that operative measures can be averted.

2 : 29-42 (July 18) 1925

Structure and Reproduction of Bacteria. A. Fontes.—p. 29.
*Pathologic Physiology of Diabetes. Pimenta Bueno.—p. 31.

Pathologic Physiology in Diabetes.—Pimenta Bueno presents arguments to sustain the view that the fundamental and single cause of diabetes is the excessive excitability of the splanchnic sympathetic. This induces vasoconstriction of the capillaries in the liver, entailing hypotension of the interstitial plasma, with aspiration of glycogen from the interior. Almost any vagotropic substance would have the same effect; it is not peculiar to insulin. Under intramuscular injection of 2.5 gm. of peptone the glycosuria dropped from 0.31 per cent. to zero in one case described, and from 2.7 per cent. to 0.74 per cent. in another after 1 gm. of peptone. He gives charts to explain the mechanism of this functional trophodynamics—the intensity of function depending on the intensity of the blood supply, other things equal.

Reconstruction of Nose. R. Pini and R. Becco.—p. 187.
Dermatosis and Syphilis. J. L. Carrera.—p. 190.

Recklinghausen's Disease with Suprarenal Deficiency.—Mainini is inclined to ascribe to a primary diffuse affection of the sympathetic system the intense neurofibromatosis with progressive asthenia and other signs of loss of suprarenal functioning. Necropsy failed to reveal any cause for the suprarenal deficiency beyond the neurofibromatosis, although the man had been addicted to alcohol and the Wassermann test was positive; there were no signs of tuberculosis.

Edema as Early Symptom of Gastric Cancer.—Vague dyspeptic disturbances in the woman of 46 and man of 36 were soon followed by edema in the legs which rapidly spread although nothing in heart or kidneys could explain the tendency to generalized dropsy. In about four months a small tumor became palpable in the woman's stomach, which rapidly developed intensely malignant features. In the man, the whole syndrome ran its course in two or three months. These cases of gastric cancer with anasarca as practically the first symptom can be differentiated only by exclusion. The cancer evidently induces a bilateral phlebitis by infection; the blood shows the type of cancer anemia. In these two recently observed cases necropsy failed to show any evidence of compression to explain the edema. There was repeated hematemesis in the second but not in the first case.

Alopecia Areata as a Sympathetic Affection. Castex and Camauer.—p. 250.
*Cancer. G. Fichera.—p. 262. Cont'd.

Form of Banti's Disease with Thrombophlebitis.—Alvarez' patient was a boy whose spleen had been slowly enlarging for seven years. There were six periods of sudden and profuse gastro-intestinal hemorrhages, with fever, and followed by ascites which was gradually resorbed each time. There were never any appreciable symptoms from the liver. The spleen grew smaller after each gastric hemorrhage. The boy is now 10, malnourished and anemic. Splenectomy was deferred in the early stages of the disease, and now it seems too grave to venture. Seven Argentine surgeons have reported a total of thirteen operative cases, but all proved fatal in a few days to a year with a single exception; this was Castaño's patient who is still in good health eight years later. Alvarez' case teaches, however, that hemorrhages and ascites do not indicate that the disease has already reached an inoperable stage. The hemorrhages may reveal merely the spleen thrombosis.

Cancer.—Fichera states that half a million persons die of cancer every year, and that Europe alone is responsible for 300,000, and North America for 95,000. England's figure is 45,000; France, 24,000; Italy, 27,000, and Argentina, 5,696. No climate or race is exempt, but women develop cancer at an earlier age than men, and the malignant disease attacks perferably organs in which there is exceptional cellular activity during their functioning. He thinks the alleged increased prevalence of cancer is more apparent than real, and is hoping much from the collective inquiry undertaken by the League of Nations.

*Casein in the Diet of White Rats. L. Savazzini.—p. .265.
Action of Insulin on Glycolysis in Vitro. O. Pico Estrada et al.—p. 275.

Autoreinfection of Hookworm.—A woman with extensive burns was constantly in the hospital for three years. She was treated for hookworm on admittance, and was apparently cured for three months. Then the ova reappeared in the stools, and were again banished. Again they reappeared after six months, and Bacigalupo then examined the finger-nail dirt, finding one normally developing ovum and two larvae. After the finger-nails were sterilized there was no further return.

Polyuria After Intracranial Lesion.—The pituitary was removed in toads or the infundibular region touched with a hot needle. This induced extreme polyuria, and the weight increased in toads deprived of the pituitary. The toad seems to be the only animal in which the secretion of the pituitary can be measured by the changes in the color of the skin.

Casein in the Diet of White Rats.—On the Osborne and Mendel complete ration (with 10 per cent. casein) the animals lost weight and developed anemia, as also when casein was given with other rations.

Primary Pyopneumocyst in Liver. Escudero and Tobias.—p. 217.
*Case of Bronzed Diabetes. I. M. Hernández and M. Benarós.—p. 223.

Stenosis of the Pylorus from a Polyp.—Four years after mammectomy for cancer, pains in the epigastrium and oppression after eating were accompanied by biologic signs of cancer (retarded glycosuria and exaggerated autolysis in the urine) and evidence of stenosis of the pylorus. The stomach was removed, but no traces of cancer were found; the tests had been misleading. The obstruction at the pylorus was due to a minute polyp.

Direct Inspection in One's Own Eye of the Blood Corpuscles and Their Movements.—Fortin asserts that with the blue light of the mercury vapor lamp it is possible to behold the circultion in one's own retina as distinctly as articles seen through the best microscope. A blue sky or a snow field reproduces similar conditions to a very slight degree. He explains the mechanism of the phenomenon, and remarks that instead of saying "A man is as old as his arteries," it would be better to say "as old as the circulation in his retina," because he can gage that himself.

Bronzed Diabetes.—The man, aged 37, presents grave diabetes, hypertrophic cirrhosis of the liver and extreme bronzing of the skin, but there is no asthenia and the blood pressure is normal. Alcoholism is the only clear pathologic antecedent. With insulin he has been rescued twice from precoma, but the condition is slowly progressing. There are no indications of hemolysis.

Long Retention of Four Months' Fetus. J. Bazán.—p. 190.
Street Venders of Eatables. A. Casotto.—p. 192.
Special Features of Influenza in Infants. Llosa.—p. *193.*

The Banti Syndrome from Congenital Syphilis.—Acuña and Maggi report a third case in which a girl apparently moribund from advanced Banti's disease recovered clinical health under treatment for the previously unsuspected or unheeded congenital syphilis. This improvement has persisted unmodified for six months to date. The girl is now 14. There had been evidently sclerogenous lesions of syphilitic origin in the viscera, with inflammation involving the peritoneum. The reds numbered 800,000, the whites 3,125, and there had been vomiting of pure blood on four occasions during the year and a half of the disease.

Sarcoma of the Eyelid.—Satanowsky gives an illustrated description of a case of melanic sarcoma of the tarsal conjunctiva successfully removed, the patient, a man, aged 60, and a case of subcutaneous leukosarcoma of the upper lid of a boy, aged 5. In this latter case the sarcoma continued its fatal course, notwithstanding two operations and roentgen-ray and radium treatment in the course of about eighteen months.

Technic for Making Iodotannic Jelly. A. J. Bandoni.—p. 253.

Hemoptysis in Hypertension.—Rossi warns against ascribing to tuberculosis what is really a hemorrhage from hypertension. The older age, the lack of fever, the large heart, the often positive Wassermann reaction, should suggest the true and nontuberculous origin. He has never encountered chronic hypertension in a tuberculous subject. He describes a few cases of nontuberculous hemoptysis; in one it has recurred twice, relieving the woman's asthma each time. Another woman has had hemoptysis six times; in another case epistaxis and hematuria have alternated with hemoptysis, nearly daily, for six weeks. In all in this group, inoculation of guinea-pigs with the sputum was constantly negative.

Secondary Enterostomy in Peritonitis and Ileus.—In cases which show the dangerous symptoms of intestinal paralysis after operations for peritonitis or ileus, Hübener advocates the performance of a secondary enterostomy. This method of treatment was used in thirty-two patients and frequently with good results. Ill effects were never observed.

Operative Treatment of Simple Fractures.—Nast-Kolb advocates surgical treatment in recent subcutaneous fractures with the following indications: (1) in fractures involving a joint and in separation of the epiphysis; (2) in transverse fracture of the forearm or the leg, and (3) in isolated fractures of the radius or the tibia, if an attempt at conservative treatment does not seem promising after five or six days. The generally accepted indications (fractures of the patella, injuries to a nerve, etc.) are not discussed.

Early Operative Treatment of Arthritis Deformans. Läwen.—p. 265.
*Osteomalacia of Sesamoid Bone. W. Müller.—p. 308.

Experimental Studies on the Treatment of Tetanus.—Guinea-pigs received a fatal dose of tetanus toxin and were then injected with different proteins and with tetanus antitoxin. Buzello and Englmann found that the animals treated with normal human or horse serum developed only a very mild disease, and recovered. Specific tetanus antitoxin, however, is more efficient. Other nonspecific proteins only delayed the manifestation of the disease.

Sequelae of Paraffin Injections.—Rose reports the cases of three women who had received injections of paraffin into the mamma tissue for cosmetic reasons. The injections had been made twelve, eighteen and twenty years, respectively, before these patients came to his notice. One patient complained of severe pain, one of pain associated with inflammation and necrosis of the skin, and the third patient had developed an adenocarcinoma. Rose has collected a further series of similar cases from the literature, and emphasizes that paraffin injections are likely to be very harmful to the patient and that their desired cosmetic effect is usually of only short duration.

Localized Osteomalacia.—Müller observed four patients with a process of osteomalacia in the sesamoid bone of the first metatarsal bone. The roentgen-ray picture shows a spotty, irregular appearance of the bone; the patient complains of severe local pain, and there is localized edema of the subcutaneous tissue. Rest and the prevention of mechanical irritation usually cure the disease. In persistent cases extirpation may be considered.

Indications for Temporary Roentgen-Ray Castration. Lüttge.—p. 306.

Pathogenesis of Melena in Infants.—Wieloch reports the case of a female infant who died under the symptoms of melena nine days after birth. Necropsy showed that an umbilical infection had resulted in thrombosis of the umbilical and portal veins.

Endocrine Condition After Roentgen-Ray Castration.—Küstner applied the Abderhalden reaction (modified by Lüttge and v. Mertz) to the serum of women in the natural menopause, of women after uterus extirpation, and of women after roentgen-ray castration. He found a positive reaction with ovarian proteins only in the last group, and he concludes that roentgen-ray treatment does not simply stop the ovarian function, but induces a pathologic endocrine function of the ovaries.

Pathologic Anatomic Findings in Angina Pectoris.—The clinical entity called angina pectoris must be strictly differentiated from aortalgias and from cardiac asthma. In all cases of typical angina pectoris, Oberndorfer found the anatomic manifestations of circulatory disturbances in that part of the left ventricle which receives its blood supply from the descending branch of the left coronary artery, that is, apex, septum and sometimes anterior wall. Anemic infarcts, scar formations and secondary aneurysms were found in these locations. The openings of the coronary arteries may be reduced in size by syphilitic aortitis; the coronary artery may be the site of syphilitic processes and thrombi, but cases are found in which no such vascular pathology explains the degenerative changes in the heart musculature. This suggests the possibility that the vascular changes are sometimes only secondary to irregularities in the vascular nervous supply and that severe but temporary spasms of the artery may lead to anemic infarcts. Anatomic changes in the ganglion cells, connected with the innervation of the cardiac vessels, are as yet unknown, but may possibly be the primary cause of angina pectoris.

Difference of the Pulse in the Right and Left Wrist.—Glintschikoff observed that the phenomenon is more frequently and more easily noticed, if the two pulses are taken while the patient keeps his arms elevated.

Wiener klinische Wochenschrift, Vienna

*Nephritis Dolorosa. C. Schneider.—p. 700.

Disinfection of Kidney Tissue.—Rosenstein attempted a disinfection of infected kidneys in the following way: The kidney was first decapsulated; then, with a pointed cautery ten or twelve fine holes were made deep into the renal tissue, and the disinfecting fluid (Rivanol) was injected through a long and fine needle into the pelvis. After a certain pressure is reached, the fluid exudes through the cautery puncture holes. The author has treated four patients in this way, and believes that the procedure is harmless, and may save kidneys which otherwise would have to be removed.

Nephritis Dolorosa.—Schneider discusses in detail the clinical picture of this disease, and reviews the different opinions on the genesis of the characteristic attacks of pain.

*Bactericidal Property of Serums. A. Tseitlin.—p. 51.
Method for Staining Negri bodies in Rabies. E. Turevitch.—p. 71.

Vaccine Skin Test in Diagnosis and Prognosis of Scarlet Fever.—Sheltenkoff prepared a polyvalent vaccine with streptococci from throat, blood, ear, mastoid process, pleura and kidney of scarlet fever patients. The vaccine contained 100 millions of bacilli in 1 c.c. He injected subcutaneously 120 scarlet fever patients with from 0.1 to 0.5 c.c. of the vaccine, or with 0.1 to 0.2 c.c. intradermally. There was no local reaction in the first five days of the disease in any instance, but a local reaction usually developed by the fifteenth or twentieth day, and persisted much longer in grave cases with complications. The same injections in twenty-eight healthy children, aged from 6 to 15, induced a positive skin reaction the next day in 65 per cent. In twenty-two children, of the same age, mostly with eruptive diseases, other than scarlet fever, the reaction was positive the next day in 27 per cent. The prognosis was favorable with a positive reaction occurring during complications. He says that a negative reaction has no diagnostic import since it occurs also in other diseases; but a positive reaction, appearing in the first five days, positively excludes scarlet fever. The reaction was always positive in convalescents. Except slight headache in a few cases, no general reaction was noted with 700 intradermal injections of 0.1 or 0.2 c.c. of the vaccine.

Bactericidal Property of Serum from Man and Animals.—Tseitlin added to 0.5 c.c. of normal serum, active or inactive, 1 drop of a culture of bacteria diluted to 1 per thousand. Horse and rabbit serum displayed a notable ability to destroy the bacilli of anthrax and diphtheria, and a slight potency for typhoid bacilli. Sodium chlorid and bismuth subnitrate enhanced the bactericidal property of the serums still more. The serum from persons with a typhoid or typhus history also proved bactericidal. Goose serum presented considerable bactericidal power for the bacilli of anthrax and diphtheria; pigeon serum only when mixed with bismuth.

*Anatomic Findings in Mongolian Idiocy. A. Gans.—p. 922.
*Sanocrysin. H. Møllgaard.—p. 926.
Alleged Efficacy of Formic Acid in Therapeutics. Van Dam.—p. 942,

The Speech After Laryngectomy.—Burger and Kaiser analyze the phonetic conditions in a man whose larynx was removed on account of cancer three years before. His speech is so good that it does not interfere with his official telephoning from Amsterdam to Munich in reporting races, etc. The speech is closer to normal when his stomach is full. He wears the cannula only daytimes; it is hidden by his beard.

The Intra-Ocular Pressure in Diabetics.—Marx states that no change in the intra-ocular pressure could be discovered in two of five patients under insulin treatment, while in the others the pressure rose. There was no rise in two diabetics after ingestion of the 50 gm. of glucose which had rapidly increased the sugar content of the blood. He urges others to continue this research, examining the intra-ocular pressure at the same time the glycemia is recorded. There did not seem to be actual parallelism between them, but the general trend seemed to be the same.

The Anatomic Findings in Mongoloid Idiocy.—Gans says that he has found up to eighty different kinds of malformation in cadavers of mongoloid idiots. The brains show the brachycephaly formation of the Chinese brains examined by Kappers, only in a more pronounced form—"more Mongolian than the Chinese." The weight of the cerebellum was always subnormal, and a bunch of nerve tissue—grey matter—was found on the median side of the flocculus. This *tuber flocculi* has been described by others as heterotopia in the cerebellum. It has been noted in congenital myoclonia, and something of the kind was evident in a chimpanzee and an orang-outang Gans examined.

Present Status of Sanocrysin Treatment.—Møllgaard presented this report at a meeting of the Utrecht branch of the Netherlands Medical Association. He reiterated that this method of treatment is an attempt to produce a chemotherapy in the Ehrlich sense, and that it is only a beginning. But it is yielding good results in many cases, and exactly in those cases in which other methods of treatment fail. The present technic has materially reduced its dangers. The rapidity with which improvement follows is a special feature of the method. Distinct improvement has been observed in 52 per cent. of the 254 cases treated in the sanatoriums of Denmark to date, but comparatively few of the patients completed the full six months' course. The percentage is 83 in those that completed the course. The danger of shock has been reduced by waiting until the febrile reaction from one dose has entirely subsided before giving another. Another point is to wait for four days when no reaction is apparent, as delayed reactions have been observed, and this brought the reaction fever into conflict with the new dose. Albuminuria as an element in the febrile reaction is transient and harmless, but albuminuria later is regarded as a contraindication for the drug until the urine is normal again. The doses have been much reduced since the first. One group of internists give 0.5 to 1 gm. at six day intervals; another group, 0.05 to 0.25 with four day intervals. Albuminuria has become much rarer with these methods, which seem to give about equal results. In moderately severe and light cases, sanocrysin treatment may be regarded as relatively harmless, but there will always be danger in the very grave cases with high fever until an antiserum can be produced that will control the acute intoxication.

Norsk Magazin for Lægevidenskaben, Oslo

86 : 917-1044 (Sept.) 1925

*Tuberculosis of the Skin. E. Bruusgaard.—p. 917.

*The Tonsils in Rheumatism. Reidar Gording.—p. 995.

Tuberculosis of the Skin.—Bruusgaard remarks that the swelling of glands back of the primary lesion usually gives the first clue to its tuberculous nature. The swollen glands are hard and movable at first, but they soon become soldered to their surroundings, and perilymphadenitis with proliferation of connective tissue develops in the depths. This differentiates it from a syphilitic lesion. He gives an illustrated description of several personal instances of primary tuberculous skin lesions in children. The course seems to be milder when the skin lesions are prominent. In these cases the skin may take an active part in the immunization process. He argues that tuberculosis passes through three stages the same as syphilis, but differs from the latter in its receptivity for repeated infection. Flaring up of old infection is more common, however, in which again it resembles syphilis. Protracted serial study of the skin manifestations of tuberculosis, in connection with simultaneous biologic immunity tests, he thinks will throw much light on tuberculosis in time.

Acute Poliomyelitis with Polyarthritis.—The girl, aged 16, developed multiple painful joint affections along with the peripheral paralysis. The polyarthritis improved under salicylates and disappeared the tenth week, but the spontaneous pains persisted for seven months, agonizing at times. The paralysis has persisted practically unmodified.

Rheumatism and the Tonsils.—Gording reports clinical and experimental research on 260 cases of joint and muscular rheumatism, all but 25 per cent. in women. A history of tonsillitis was known in only thirty of the 108 cases of primary chronic polyarthritis, and in thirty-four of the 107 muscular and nervous rheumatism cases. The average age at the onset in the tonsillitis cases in both groups was 27, and in the nontonsil cases 43 and 44. In the thirty-four cases treated with tonsillectomy, improvement followed in twenty-two but not in the others.

*Tubercle Bacilli in the Spinal Fluid. K. A. Jensen.—p. 710.
Acute Leukemia in Young Woman. R. Thede.—p. 711.

The Spinal Fluid in Sciatica.—Neel declares that lumbar puncture is indispensable for a complete study of the etiology of sciatica. The findings were more or less pathologic in the eighteen cases he describes, but three of the patients had a history of syphilis.

Tubercle Bacilli in the Spinal Fluid.—Jensen obtained positive cultures with Petroff's medium in fifteen of twenty-two cases of tuberculous meningitis. It required only from ten to thirty-six days in fourteen of the cases. He prefers Bender's picric acid modification to the original Ziehl-Neelsen staining method. It materially shortens the time required for the microscope.

*Medical Treatment of Glaucoma. H. Larsen.—p. 775.
*Cancer or Tuberculosis. C. Gram.—p. 782.
*Changes in the Clinical Picture of Alcoholism. A. Wimmer.—p. 784.

Medical Treatment of Glaucoma.—This is Larsen's lecture in competition for the chair of ophthalmology. He says of subconjunctival injection of epinephrin—which Hamburger has found effectual in reducing the intra-ocular pressure to an extent that renders it amenable to miotics afterward—that it is still in the tentative stage, as likewise dry sodium chlorid by the mouth or vein. The reliance is still on miotics, but he reiterates that it is not enough to order the proper treatment; the important point is to see that the treatment is properly applied for as long as needed. This is particularly difficult when daily instillations have to be kept up for years, as the disturbances progress so insidiously in glaucoma. But conservative treatment is regaining ground more and more. Bright light and reading fine print aid in reducing glaucoma; conditions dilating the pupil should be avoided. Larsen has one patient who has had glaucoma in one eye for nine years. During the last seven he has had 2 per cent. pilocarpin instilled three times a day, and the tension keeps 26 mm., vision 6:6, although the disk shows some cupping. Van der Hoeve's patient was kept with normal vision in this way for fifteen years.

Cancer or Tuberculosis?—A previously robust man of 43 had a supposed primary tuberculous process in the testis removed. Three months later symptoms suggesting a spinal cord tumor or syringomyelia developed, and necropsy revealed numerous metastases from the primary lesion in the testis. No trace of tuberculosis was found. The main symptoms were from a large metastatic tumor in the sacrum.

Alcoholism in Copenhagen.—Wimmer brings statistics down to date. He ascribes the lower number of cases of delirium tremens to the high price of liquor under the 1917 law. From 321 cases in 1910, it dropped to twenty-four in 1923. The reduction is entirely in the group of casual drinkers. The cases of alcoholism now are mainly in persons with psychopathic degeneration, the feebleminded and epileptics, and the chronic habitual drinkers. This change in the character of the cases of alcoholism in institutions, since antialcohol legislation, is evident in France and Germany as well as in Denmark, he says. Total prohibition would not make the degenerates normal, and he thinks it is preposterous to inflict total prohibition on the entire populace merely to benefit the comparatively few chronic habitual drinkers.

THE WASSERMANN REACTION AND THE PATIENT

RESULT OF ROUTINE TREATMENT OF ELEVEN HUNDRED AND SEVENTY CASES OF SYPHILIS *

FRANK C. KNOWLES, M.D.
JOHN B. LUDY, M.D.
AND
HENRY B. DECKER, M.D.
PHILADELPHIA

The treatment of syphilis is usually conducted in courses with intervals during which no treatment is given. The principle of the courses is that both arsenicals and mercurials are employed and in doses calculated to destroy *Spirochaeta pallida* without harming the patient.

Our method of treatment is the same for the several types of syphilis. To men we give 0.6 gm. of neo-arsphenamin at the first injection, followed by five weekly injections of 0.9 gm., making a total of 5.1 gm. To women, six weekly doses of 0.6 gm. are given, a total of 3.6 gm.

The arsenical course is immediately followed by the mercurial course, which consists of the intragluteal injection of 1 grain (0.065 gm.) of mercuric salicylate at weekly intervals for twelve doses. During the period of mercury medication we give potassium iodid by mouth in 10 grain (0.65 gm.) doses three times daily.

A rest of one month is then taken, the Wassermann test is done, and the same course of treatment repeated, except for the giving of a like total amount (3.6 gm.) of neo-arsphenamin to men and women. Iodids and mercury are given as in the first course.

After the completion of this course a rest of another month is given, at the completion of which the patient is reexamined, and a Wassermann test is taken. The clinical findings in conjunction with the serologic test now determine the patient's future treatment.

Attention is called to the fact that all our patients are examined by a competent internist, detailed from the medical service, at the commencement of treatment and at the completion of the second series of our course.

We tell all our patients that they must take forty weeks of treatment. This is something tangible, and the chances are that they are likely to take at least this amount of treatment either at our clinic or wherever they may migrate.

From April, 1923, to February, 1925, we treated in our clinic 1,170 cases, in 380 of which treatment was completed, and in 790, allowed to lapse. We numbered 134 cases of primary syphilis. Of these, two were suprapubic chancres, one was a chancre of the tonsil, one a chancre of the lip, and the chancre in the remainder was located on some portion of the genital tract.

In twenty-seven cases, eighteen weeks of treatment was completed. At the beginning of treatment twelve of these had a plus four, two a plus three, one a plus two, two a plus one and ten a negative Wassermann reaction. Dark-field examination of the chancre showed spirochetes in thirteen cases, was negative in three cases, and not done in eleven cases.

After eighteen weeks of treatment and a rest of one month, the Wassermann reaction was as follows: two cases, plus four; one case, plus three; one case, plus two; two cases, plus one; twenty-one cases, negative.

In seven cases, forty weeks' treatment was completed. The Wassermann reaction one month later showed: two cases, plus four; one case, plus one; four cases, negative. Two of these remained negative for one year and had negative cerebrospinal fluids. The remaining two were negative for six months.

In eight of the primary cases the patients had been treated prior to coming to our clinic. Four had less than 5 gm., and four had between 5 and 10 gm. of neo-arsphenamin.

It will be of interest to note at what period treatment in the primary cases lapsed: in fourteen cases after the first injection of neo-arsphenamin, in fifteen after the second, in nine after the third, in twelve after the fourth, in seven after the fifth and in eight after the sixth, making a total of sixty-five cases in which treatment lapsed during their arsenical course; in sixteen cases after the first injection of mercuric salicylate, in twelve after the third, in six after the fifth and in eight after the seventh, making a total of forty-two cases in which treatment lapsed during the mercuric salicylate course.

There were 134 patients with secondary syphilis. Of these forty-seven took eighteen weeks' treatment, sixteen took forty weeks and in eighty-seven treatment lapsed.

The Wassermann reaction of the forty-seven cases at the beginning of treatment was as follows: thirty-nine, plus four; three, plus three; three, plus two; one, plus one, and one, negative.

The Wassermann reaction taken one month after the completion of eighteen weeks of treatment showed: ten cases, plus four; one case, plus three; one case, plus two; one case, plus one; one case, plus minus, and thirty-three cases, negative.

The Wassermann reaction of those patients in whom forty weeks' treatment was completed showed: one case, plus four; one case, plus three; one case, plus one, and thirteen cases, negative.

---

* From the Pennsylvania Hospital.

* Read before the Section on Dermatology and Syphilology at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

Ten patients received previous treatment; eight, less than 5 gm., and two, between 5 and 10 gm. of neo-arsphenamin.

In the cases in this group treatment lapsed as follows: in twelve cases after the first injection of neo-arsphenamin, in eleven after the second, in fourteen after the third, in six after the fourth, in nine after the fifth and in six cases after the sixth, making a total of fifty-eight cases; in eight cases after the first injection of mercuric salicylate, in eight after the third, in seven after the fifth, in four after the seventh and in two after the ninth, making a total of twenty-nine cases.

TABLE 1.—*Wassermann Reactions of Three Hundred and Eighty Patients in Whom Treatment Was Completed*

1,170 { 380—treatment completed / 790—treatment lapsed

Primary: Dark field + in 13 / — in 3

	Plus 4	Plus 3	Plus 2	Plus 1	±	—	Total
Primary	12	2	1	2		10	27
Secondary	39	3	3	1		1	47
Tertiary	193	35	30	23	2	23	306
Total	244	40	34	26	2	34	386
			After 18 Weeks				
Primary	2	1	1	2		21	27
Secondary	10	1	1	1		34	47
Tertiary	4		18	139		145	306
Total	16	2	20	142		200	380
			After 40 Weeks				
Primary	2			1		4	7
Secondary	1	1		1		13	16
Tertiary			7	40		37	93
Total	3	1	7	51		54	116

We had 902 cases of tertiary syphilis. Of these 306 were given eighteen weeks of treatment; ninety-three, forty weeks; in 596 treatment lapsed. Of this number 166 cases were latent; forty-nine presented cutaneous lesions common to tertiary syphilis; twenty-three were cardiovascular; nine, osseous; thirteen, visceral; twenty-five, neurosyphilitic, and two, paretic; nine patients had tabes dorsalis. Five patients had optic atrophy, three had syphilitic stricture of the rectum and three had asthma.

The Wassermann reactions in the tertiary cases were as follows: 193, plus four; thirty-five, plus three; thirty, plus two; twenty-three, plus one; two, plus minus; twenty-three, negative.

One month after the completion of eighteen weeks of treatment, 113 cases became negative from positive; forty-one, weakly positive from strongly positive; eighteen, moderately positive from strongly positive; ninety-eight revealed no change, remaining positive; nineteen, no change, remaining negative; five became negative from a positive; four, strongly positive from weakly positive.

After forty weeks of treatment: thirty-four cases changed from positive to negative; seventeen, from strongly positive to weakly positive; seven, from strongly positive to moderately positive; thirty-two remained positive; three, negative. The previous treatment given was: twenty-two cases, up to 2.5 grains (0.16 gm.) of neo-arsphenamin; forty-six, up to 5 grains (0.32 gm.); twenty-seven, up to 7.5 grains (0.49 gm.); fifty-one, up to 10 grains (0.65 gm.). Seven patients were given from one to three mercurial injections.

Treatment lapsed in the following fashion: in ninety cases after the first injection of neo-arsphenamin; in fifty-nine after the second, in fifty-five after the third, in forty-seven after the fourth, in thirty-nine after the fifth and in sixty-one after the sixth, making a total of 351 cases in which treatment lapsed during the period of arsenical administration; in sixty-five cases treatment lapsed after the first injection of mercuric salicylate; in eighty-eight after the third, in forty-two after the fifth, in twenty-seven after the seventh, in nineteen after the ninth and in four after the eleventh, making a total of 245 cases in which treatment lapsed during the mercury course.

Negroes comprised 65 per cent. of the patients in the clinic; 20 per cent. were seafaring men, and the remaining 15 per cent. were Americans of rather recent immigration.

The seamen seldom were with us for more than one month. The negroes usually continued with us as long as their symptoms were distressing, after which they too disappeared. Our admission averages forty-eight new patients a month and we treat between 175 and 215 a week—our last treatment night the patients numbered 193.

We have no serious reactions to report. Several cases of vasomotor disturbance manifested by flushing of the face and tingling of the extremities, with dizziness and vomiting, were noted. We had two cases of dermatitis, one developing after the third injection of neo-arsphenamin and the other after the first mercurial injection. We report twenty cases of jaundice which developed between the third and the twelfth injections of mercuric salicylate.

After the first four doses of neo-arsphenamin, 37 per cent. of our patients with primary syphilis, 33 per cent. of those with secondary syphilis and 27 per cent of those with tertiary syphilis, a total of 344 patients, or 29 per cent., disappeared, the four doses of neo-arsphenamin totaling 2.4 gm.

This is certainly a regrettable feature, and it is a question whether this little treatment, though sufficient to cause the symptoms to disappear, is not worse than none at all. If there is ever a time for arsphenamin treatment, it is certainly during the first year.

TABLE 2.—*Lapses Following First and Second Courses of Treatment*

	Lapses Following Injections of Neo-Arsphenamin						
	1	2	3	4	5	6	Total
Primary	14	15	9	12	7	8	65

Tertiary	90	59	55	47	39	61	351
Total	116	85	78	65	55	75	474
	Lapses Following Injections of Mercuric Salicylate						
	1	3	5	7	9	11	Total
Primary	16	12	6	8	.	..	42
Secondary	8	8	7	4	2	..	29
Tertiary	65	88	42	27	19	4	245
Total	89	108	55	39	21	4	316

In the majority of patients taking the mercurial course, treatment lapsed after the second time (62 per cent.), and the reasons given were discomfort caused by the injection Mercury is, of course, the time-honored remedy for syphilis. After holding first place for centuries it suffered a temporary eclipse in 1910 (arsphenamin eclipse); since then it has come back into favor, and many workers assert that mercury is after all the best specific for syphilis.

The truth lies between this view and that of 1910, when arsphenamin was all sufficient.

The question of moment is not the effect that mercury and arsenic have on the prognosis of syphilis; the question in my mind is what will be the result to the patient of a treatment that so rapidly controls symptoms and thereby makes for so many delinquencies.

SUMMARY

1. Of 1,170 cases of syphilis admitted for treatment, eighteen weeks' treatment was completed in 380, and forty weeks in 116; treatment lapsed in 790.
2. Of those patients in whom at least one course of treatment was completed, 244 originally had a strongly positive Wassermann reaction; seventy-four, moderately positive; twenty-six, weakly positive; two, doubtful, and thirty-four, negative.
3. After eighteen weeks of treatment the reactions of sixteen were strongly positive; of twenty-two, moderately positive; of 142, weakly positive, and of 200, negative.
4. Of the 116 in whom forty weeks' treatment was completed, three had a strongly positive reaction; eight, moderately positive; fifty-one, weakly positive, and fifty-four, negative.
5. Treatment lapsed in 474 patients during the course of neo-arsphenamin and in 316 during the course of mercuric salicylate.
6. A little more than one third of our patients were women. Only fifteen children were treated in this series.
7. More than one half of the patients (65 per cent.) were negroes, and many of the others were of the lowest social stratum and seafaring men.
8. It is indeed unfortunate that less than one third of our patients completed eighteen weeks of treatment and only one tenth forty weeks, notwithstanding a follow-up system of letters and visits made by a competent full time social service worker and her assistant.

EFFECT OF TREATMENT ON SPINAL FLUID IN CEREBROSPINAL SYPHILIS

CRITICAL ANALYSIS OF ONE THOUSAND SPINAL FLUID EXAMINATIONS *

UDO J. WILE, M.D.
AND
HARTHER L. KEIM, M.D.
Professor and Assistant Professor, Respectively, of Dermatology and Syphilology, University of Michigan Medical School
ANN ARBOR, MICH.

In 1919, one of us (U. J. W.) together with C. K. Hasley, in discussing the question of serologic cure in syphilis, expressed the belief that this did not necessarily parallel clinical cure, and that a positive Wassermann reaction in the blood in cases with a background of intensive treatment not only frequently accompanied clinical cure, but was also not inconsistent with the general good health of the person.

Our studies at that time were based on the comparison of various methods of performing the Wassermann reaction, and these studies tended to show that doubtful cases were either positive or negative, depending on various laboratory factors and technic, and on different types of reactions that are used.

Within the last two years, our observations on patients showing striking improvement in cases of cerebrospinal syphilis under tryparsamide, with spinal fluid changes that were practically unchanged by such treatment, have strengthened our belief in the nonparallelism in certain cases of biologic and clinical cure. Recent reports on the treatment of general paresis and other forms of cerebrospinal syphilis, not only with tryparsamide but also with malarial plasmodia, substantiate these findings; namely, that extraordinary clinical betterment may frequently take place with no corresponding change coincident with such betterment in the spinal fluid and blood.

Table 1.—*Clinically Improved After Treatment*

Type of Involvement	Number of Cases	Average Number of Punctures	Pleocytosis Reduced	Organic Solids Diminished	Gold Curve Reduced to Negative	Serology Returned to Normal
General paresis	16	10	5	4	5	0
Tabes dorsalis	9	6	5	2	2	1
Diffuse cerebrospinal syphilis (late)	29	8	10	9	3	3
Diffuse cerebrospinal syphilis (early)	19	6	14	10	15	14

In the present study, we offer an analysis of 1,000 spinal fluid examinations which have been made in 148 cases that we have been able to control, first, from the standpoint of clinical betterment or the reverse, and further, in which we have been able to check each test by a triple examination. In other words, every spinal fluid in this series of study has had two Wassermann reactions done, one with incubation of one hour checked against an eighteen hour incubation, and both of these checked against a Kahn precipitation test on the spinal fluid.

The majority of these cases have been those in which repeated lumbar punctures have been made in the course of the intensive treatment.

Of the 148 cases studied, thirty-nine are classified as paresis; twenty-seven, as tabes; nineteen, as early diffuse cerebrospinal syphilis, and sixty-three as the late type of a diffuse cerebrospinal disease. We have based this classification on clinical findings, rather than on serologic tests. The treatment that these patients have had has consisted of the intravenous administration of the various arsphenamin derivatives; intraspinal treatment employing the method of direct treatment, which has been used by us for the last fifteen years; tryparsamide; mercury ordinarily in the form of inunctions; potassium iodid by mouth, and, in a few selected cases, bismuth in place of mercury. The amount of treatment in as large a group as this naturally varied within wide limits. The largest amount of treatment is found in a patient who received a hundred intravenous treatments of arsphenamin during the past two years (not from us). On the other hand, in one of our cases, the intravenous administration was limited to as small a number as two injections, plus other forms of therapy.

On the average, leaving out the amount of treatment that the patients had received prior to their admittance to our service, all the patients of this group have had several months of intravenous treatment, either with arsphenamin or with tryparsamide, also intradural treatment, and all had received a considerable amount of mercury over several months. Twenty-six of the entire number have been under our observation and treatment for from two to five years.

---

* Studies and contributions of the Department of Dermatology and Syphilology of the University of Michigan, service of Dr Udo J. Wile.

* Read before the Section on Dermatology and Syphilology at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

In studying our cases from the point of view of a critical analysis of the effect of treatment on the biologic reaction in the spinal fluid, we have thought it advisable to group the cases into those in which improvement was seen, and into those in which no improvement was seen following treatment. As may be seen by Table 1, sixteen cases of general paresis in which an average of ten lumbar punctures had been performed showed a reduction of lymphocytic element in five, a slight reduction of organic solids in four, alteration of the gold curve in five, and serology changed to negative in not a single case.

Table 2.—*Cases Showing No Clinical Improvement After Treatment*

Type of Involvement	Number of Cases	Average Number of Punctures	Pleocytosis Reduced	Organic Solids Diminished	Gold Curve Reduced to Negative	Serology Returned to Normal
General paresis	23	8	8	4	3	0
Tabes dorsalis	18	7	7	6	3	2
Diffuse cerebrospinal syphilis (late)	34	4	8	6	5	4

In connection with the gold curve, this showed alteration, but not flat reduction; and as such is frequently seen in the period of remission with or without treatment, this finding is of no significant value.

To sum up the cases of general paresis, therefore, which had improved clinically, the only change of any note in the spinal fluid is the reduction of the pleocytosis in one third of the entire group. The effect, therefore, of treatment on the picture of the spinal fluid in this group, after eighteen months in which an average of ten punctures was made, may be said to have been negligible.

Turning now to the cases of tabes (Table 1), in nine cases puncture was done, on the average, six times; a reduction of pleocytosis occurred in five; the organic solids were diminished in two; an alteration of the gold curve was seen in two, and positive serology changed to negative in one. The changes, therefore, in tabes amost parallel those of general paresis. These patients had all markedly improved clinically, and their clinical betterment showed no striking change in the spinal fluid toward the normal status.

Turning now to the diffuse type of cerebrospinal syphilis occurring late or in the period of latency, we find that twenty-nine cases progressed toward clinical betterment or cure during the period of observation. Included in this group were cases of posterolateral sclerosis, spastic paraplegia and myelitis. In this group, puncture was done, on the average, eight times; reduction of the lymphocytes was seen in ten; reduction of the organic solids in nine; the gold curve was changed in fourteen, and reduced to normal in three, and the Wassermann reaction became negative in three.

Summing this up, we find here a slightly greater tendency toward a reduction to normal, paralleling a symptomatic cure under the influence of intensive treatment.

In the group of early acute involvement of the cerebrospinal system, we have nineteen cases that improved clinically under treatment (Table 1). In this group there was an average of six punctures; fourteen showed a marked reduction in the number of lymphocytes; ten showed a diminution of organic solids; the gold curve became flat in ten, and approached the normal in the remaining five. The Wassermann reaction in the spinal fluid became negative in fourteen of this group with all three tests.

From an analysis of the last group, it is evident that a greater degree of parallelism exists between serologic and clinical cure than pertains to the other three groups of cases. We are of the opinion that included in this group are several cases in which the changes in the spinal fluid are of as evanescent a character as is the exanthematous roseola. Many of the cases of this type show a considerable deviation from the normal in the spinal fluid during the exanthematous period of the disease. These changes in some cases are quite striking. They tend, however, to respond so readily to the general treatment directed toward the systemic infection that they may be regarded possibly as cerebrospinal enanthems. That they may bear a distinct relation in ineffectively treated cases to late more serious sequelae is more than a likely hypothesis.

Of our entire group studied, seventy-five cases showed no improvement clinically after treatment. In this group, however, are included some in whom clinical betterment was impossible to determine, as they were asymptomatic when first seen.

Of this number, twenty-three cases of paresis, in which an average number of eight lumbar punctures were made, showed a reduction (Table 2) of lymphocytes in eight, organic solids diminished in four, a reduction of the gold curve to negative in three, and a negative serology in not a single case with all three tests.

Eighteen cases of tabes of this group, having an average number of seven punctures, showed a reduction of lymphocytes in seven, a diminution of organic solids in six, a gold curve reduced to negative in three, and a Wassermann reaction reduced to negative in two. In thirty-four cases of diffuse cerebrospinal syphilis occurring late in the course of the disease, puncture was done, on the average, four times; pleocytosis was influenced by reduction in eight; organic solids diminished in six; a gold curve reduced to negative in five, and a Wassermann reaction made negative in four.

Table 3.—*Effect of Treatment in Cerebrospinal Syphilis During Period of Exanthem* *

Number of Puncture	Effect on Pleocytosis	Effect on Organic Solids	Change in Gold Curve	Serology Kahn	Serology Wassermann	Serology Wassermann

First	125	+	11222100000	++++	+++	++++
Sixth	22	—	00000000000	—	—	—

* Fourteen cases studied, five typical examples shown.

From an analysis of this table, it is evident that a considerable degree of apparent change can occur in spinal fluid findings which is not paralleled by a corresponding clinical improvement. In the main, however, a general tendency toward fixation in the spinal fluid in all its abnormal findings is characteristic of this group as it is of the other.

As illustrating the remarkable effect of treatment in cases of early acute cerebrospinal syphilis occurring during the exanthem, we have studied fourteen cases, of which the five most typical are shown in Table 3. As may be seen here, practically all these cases showed seriously changed fluids at the outset. In three of this group at least, the changes were those ordinarily associted with severe parenchymatous disease. All of this group became completely negative incident to the systemic treatment directed to the disease, as well as to the special treatment directed to the nervous system.

A picture striking in comparison with this is seen in Table 4, which illustrates the effect of treatment on early cerebrospinal syphilis occurring after the exanthematous period or with so-called secondary recurrences. In this group, we are evidently dealing with a far more serious type of involvement, as may be seen by the fact that in not a single case was the serology of the spinal fluid in any way influenced after many months of treatment and observation.

In connection with all the cases here discussed, attention should be called to the fact that our findings are not established on the basis of single lumbar puncture, but are taken from the study of repeated spinal fluid findings. The relation of the group shown in Table 4, in which little or no effect is seen on spinal fluid findings, to later more serious sequelae, becomes more than a pertinent suggestion.

Table 4.—*Effect of Treatment on Early Cerebrospinal Syphilis After Exanthematous Period or with Recurrences*

CONCLUSIONS

1. Deviations from the normal in the spinal fluid, in acute cases of cerebrospinal syphilis occurring during the exanthematous period, tend to be reduced to normal, parallel with clinical improvement following intensive treatment.

2. This tendency toward normality in the abnormal spinal fluid is less noticeable in diffuse cerebrospinal syphilis occurring in the period of latency or with recurrences.

3. In cases of parenchymatous disease of the cerebrospinal system, notably in tabes and paresis, there is little or no simultaneous tendency toward a reduction of the diseased fluid to the normal, even in cases in which clinical improvement is striking.

4. The most easily influenced constituent of the diseased fluid in all types of cases is its lymphocytic content; less easily influenced, although still reducible in the acute cases, is the increase in globulin and albumin.

5. The colloidal gold curve may be reduced to normal in the early cases, but is influenced with difficulty by treatment in the later phases of the disease.

6. The least influenced by treatment in our series of cases is the Wassermann reaction. This tends to be reduced to normal in the very early or acute cases, but seems to be uninfluenced and more likely to be fixed in the late cases than any other of the changed constituents of the spinal fluid.

CLINICAL MANAGEMENT AND RESPONSE OF TABETIC PATIENT *

JOHN H. STOKES, M.D.
AND
LOREN W. SHAFFER, M.D.
PHILADELPHIA

A year ago we[1] reported the aggregate results secured in neurosyphilis by standard methods of treatment, including a soluble mercurial salt intramuscularly or inunctions, sodium iodid intravenously, and arsphenamin intravenously and intraspinally. These results are summarized for reference in Chart 1. Interesting observations on the general management of the neurosyphilitic patient, and his symptomatic response to treatment, could not be included in the previous paper for lack of space. These are now made the material for the present communication. The case basis for the charts here presented is in large part a series of 170 tabetic patients observed in the Section on Dermatology and Syphilology of the Mayo Clinic for from two to seven years.

Certain basic facts should be recalled in connection with the treatment of the tabetic patient. The pathology of neurosyphilis at the outset is meningeal. The prognosis of meningeal neurosyphilis is the best of the various types—excellent, in fact. The earliest *clinical evidence of neurosyphilis, in the tabetic-to-be*, is a rise in cell count in the spinal fluid. The logical preventive treatment of the tabetic-to-be begins with the detection, by routine spinal fluid examination, of his asymptomatic neurosyphilis during the secondary and latent periods. From 40 to 70 per cent. only represent the range of estimates, in the literature, of the proportion of definitely diagnosticated tabes dorsalis that has a positive blood Wassermann reaction. The detection and preventive management of neurosyphilis cannot therefore be left wholly to the finding of a positive blood Wassermann test.

Paresthesias, pains and sensory disturbances furnish, with pupillary abnormalities, the first clinical warnings of tabes in the large majority of cases. The involvement of the sensory spinal ganglion root by the meningeal inflammation (Nageotte, Richter[2]), which precedes the degenerative changes in the posterior columns of the cord, and basilar meningeal changes in the brain, furnish the pathologic background for these early warnings. The so-called "signs" of tabes, as distinguished from the symptoms, are degeneration marks, or scars, and as such cannot be either the ideal guides to the existence of the process, or the best indicators of its treatability or arrest. It is to be expected that the late tabetic patient will carry ineradicable evidence of the degenerative aspects of the process. Failure to restore pupillary mobility or lost reflexes, or to

"cure" an ataxia, cannot be taken, therefore, as a fair test of the possibilities of modern neurosyphilotherapy.

The attention of the profession should therefore be focused consistently on the subjective symptomatology of early tabes, and when any of its leading points are developed in a case history, a quick search for early signs should be made as a routine. Lightning pains will then no longer pass as "rheumatism" or "neuritis" in the face of absent pupillary light reflexes or knee jerks; "slow" bladders be called "stricture"; gastric crises be operated on as gallbladder attacks; failing vision from optic atrophy be given glasses, and malperforans diagnosed "corns." A summary of our observations on the symptomatology of neurosyphilis, preponderantly of the tabetic type, is given in Chart 2.

The prognosis of neurosyphilitic symptoms in general depends on the ratio of inflammation to degeneration at the time treatment is begun. We know of no direct means by which such an estimate can be made with accuracy. Baughn and Stokes, in an unpublished study (1920), recognized the better prognosis of patients presenting a relatively high cell count in the spinal fluid combined with a second zone gold solution curve, and the finding has in general proved a useful, though by no means infallible, clue to the amenability of a given case to treatment. The difficulty of determining the vascular element in a neurosyphilitic complex reduces prognostic accuracy, and is the source of many unexpected accidents. The obviously degenerative complexes and signs, such as ataxia, deafness, and optic atrophy, make the poorest therapeutic response. On the other hand, the neurogenous or "cord" bladder, which one would be inclined to interpret *a priori* as the expression of a degenerative lesion, may show a surprisingly good restoration of function under treatment, while lightning pains, which one would be inclined to interpret as an irritative phenomenon associated with inflammation of the dorsal roots, may prove most intractable, and persist long after such signs of active meningitis as an increased cell count in the spinal fluid have disappeared. Symptoms dependent on basilar meningeal involvement, such as ptosis and diplopia, vertigo and headache, are in our experience quite responsive to treatment, possibly because a combination of rich blood supply and meningeal involvement makes them comparatively accessible.

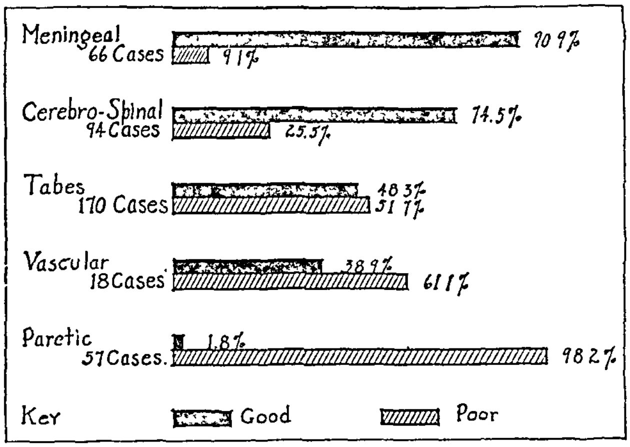

Chart 1.—Results in treatment of neurosyphilis.

The test of prognosis, then, lies in treatment itself, so to speak, and predictions should be made with caution, albeit in a hopeful tone. It is perhaps more necessary, however, to warn the older generation of physicians, if one may be so presumptuous, not to be too pessimistic, and to concede the value of selection and a preventive point of view in dealing with tabetic neurosyphilis.

The general methods of treatment responsible for the results summarized in Charts 3 to 8 may be characterized as follows: The patient is individualized to the highest degree if he is old, or his case is acute or late. He is systematized determinedly but not irrationally, if his case is early, his signs of recent development, his spinal fluid cell count not too high, or his symptomatic progress not too rapidly unfavorable. Arsphenamin is used in treatment, not neo-arsphenamin, except when the latter is employed in the advanced case for "tonic" effects. The Swift-Ellis-Ogilvie intraspinal therapy is often but not always a necessary part of the treatment, and produces results which, while not spectacular, are, to our minds, definitely superior to those obtainable in certain cases by other advocated technics. Intraspinal therapy is never resorted to without a previous trial of systemic treatment, amounting to one or two six or eight injection courses of arsphenamin. Mercury is used simultaneously with arsphenamin if the patient is in reasonably good condition.[3] It is used for from ten to thirty days before the arsphenamin in acute or rapidly progressive cases. Soluble and not insoluble mercurial salts are employed intramuscularly—by preference mercuric succinimid in one-sixth grain (0.011 gm.) doses five times a week for a course of thirty injections. Mercuric salicylate, the choice of the general practitioner, and calomel, the heroic mercurial, are seldom, if ever, used. The interim treatment between arsphenamin courses (three to four months' interval) is occupied by a rest period of one month, followed by forty 4-gram, 30 to 50 grain mercurial inunctions, and a rest period of another month, when the arsphenamin is again resumed.

The "paper control" of the case by examination of the spinal fluid before or after a course of treatment, or both in the earlier months of treatment, is insisted on as one of the best guides, though not an infallible one, to the progress of the case. A determined effort is made to reduce the spinal fluid to normal as indicated by the "four tests"[4] and to keep it there. But this effort is never pushed in a machine-like fashion, regardless of the complexion of the individual case. The value of complete rest from treatment, usually after the third course, is appreciated and utilized in bringing down to normal occasional "paper" findings and symptoms which persist after reasonably intensive treatment. All prolonged rest periods are, however, controlled by periodic neurologic examination as well as spinal fluid tests, the former being important in those patients who, in spite of negative serologic findings, continue their degenerative or symptomatic progress (seronegative tabes includes especially gastric crises, Charcot joint cases, and patients with associated cerebral vascular lesions). Iodid is used intravenously, synchronously with the mercurial in the form of a 10 per cent.

---

[3] Our experience with bismuth in neurosyphilis does not warrant conclusions. Although the literature is becoming voluminous on the effects of treatment with bismuth in syphilis in general, the references to its value in tabes are few and the case series small. Saethre (Norsk. Mag. f. Lægevidensk **85**: 126-134 [Feb.] 1924) and H. Boesch (Schweiz. med. Wchnschr. **53**: 1059, 1923) report very favorable symptomatic improvement in the majority of seventeen cases. Artom (Policlinico **30**: 527-530 [April 23] 1923) reports negative results in three cases. Jeanselme (Presse méd. **32**: 245-246 [March 19] 1924) and his co-workers report the absence of bismuth in the spinal fluid, as shown by chemical analysis in a study of thirty cases. Foster and Smith (J. Nerv. & Mental Dis. Nov., 1924, p. 472) report the use of bismuth in twenty-three cases of tabes observed for from four to twelve months. They report improvement in gait and subjective symptoms, especially lightning pains, in the majority of cases.

[4] Wassermann test on 0.2 and 1 c.c., globulin estimation, cell count and colloidal test.

sterile solution of sodium iodid, 10 gm. daily five times a week, after two or three days' preliminary administration of the drug by mouth to detect idiosyncrasy. This method was adopted as a result of the studies of Osborne[5] on the increased concentration of iodid in the spinal fluid after intravenous administration, and does away with much of the gastro-intestinal load under which the patient labors who is at one and the same time receiving arsphenamin, mercury and iodid in large doses.

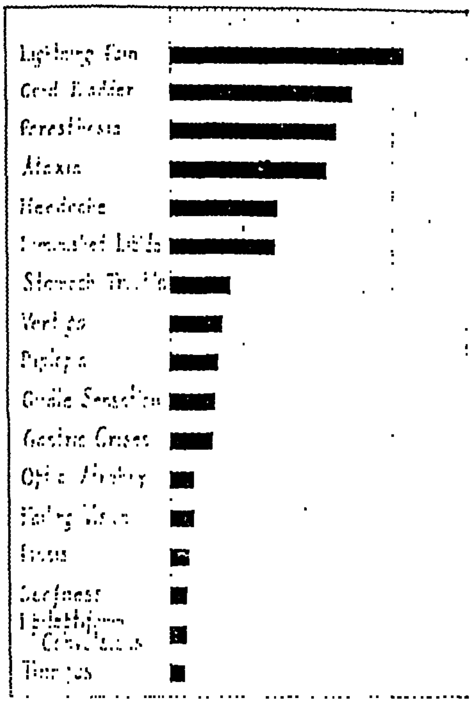

Chart 2.—Relative frequency of common symptoms in neurosyphilis as a major complaint. One space equals three cases.

We recognize distinctly a resistance-building or conserving factor in the management of the tabetic patient which sometimes transcends in its importance the mere use of antisyphilitic medicaments. Foremost of the conserving measures we would place attention to the tabetic kidney and bladder, whose function is often gravely impaired. Measures to drain by catheter an atonic infected bladder in order to improve renal function, and to restore proper bladder habits by self-training and effort, may be actually life-saving in their value. The removal of foci of infection may rid the patient of a predisposing cause of persistent lightning pains, relieve an embarrassed kidney, and improve a general debility. The reversal of intestinal flora, by *B. acidophilus* and lactose, the use of the laxative diet, fluids, oil enemas, and reduction of protein in the food, may bring about substantial results by controlling the atonic constipation and intestinal putrefaction of the late tabetic patient. In the field of direct drug therapy, we would emphasize the value of the prolonged course of small doses of neo-arsphenamin, in raising the general tone of the late or aged tabetic patient. A moderate dose, from 0.3 to 0.5 gm. of this drug, weekly, has often much more effect through its stimulation of the general resistance mechanism of the patient than do much larger doses. The use of small doses of neo-arsphenamin in early tabetic patients, however, without suitable reinforcement with mercury and iodid, is to be deprecated as predisposing to occasional serious relapse and reactivation of the process when treatment is temporarily suspended.

SYMPTOMS

The following symptoms have been selected from the series shown in Chart 3, as deserving brief special discussion.

"Stomach Trouble."—This symptom, whose prominence among the complaints of neurosyphilitic patients was brought out in a study by Stokes and Brown,[6] responds with gratifying promptness in a high proportion of cases (Chart 4), and indirectly, through restoration of appetite and weight gain, promotes the general favorable progress of the patient. No special management is required to bring about the effect. It should be emphasized that the symptoms may be due to duodenal ulcer, and that they may recur following remission, without any apparent connection with the progress of the neurosyphilis. In such cases, after diagnosis, operation may be required for relief.

Lightning Pains.—Most patients can be assured of some degree of amelioration of this symptom, the proportion of fair, good and excellent results aggregating 73 per cent. (Chart 5). Excellent results, however, were rated at only 16 per cent. The notorious persistence of lightning pains after the apparent arrest of the degenerative process in some cases is one of the trying features of late tabes. We noted occasional relief after courses of mercuric succinimid and sodium iodid when other treatment seemed without effect. The most unexpected measures seem at times to afford temporary relief, including even ultraviolet irradiation (O'Leary). The most definite predisposing factor is infection, and patients who are usually free of pains suffer exacerbations if they develop colds, bronchitis and other causes of rise in temperature. The removal

of focal infections sometimes, but by no means always, has a striking effect. Lightning pains are a valuable clue to early relapse, and the patient in whom they have disappeared under treatment should be warned to make even a mild recurrence the signal for a reconsideration. The relation of the pains to infections probably explains the value of change to a warm climate for the elderly tabetic patient who is housebound by repeated severe attacks during the winter months. In two or three obstinate cases observed by us, stripping of the coats of the femoral artery (Leriche operation) has failed to afford relief.

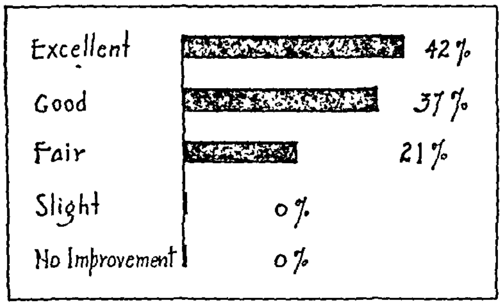

Chart 4.—Clinical response of stomach trouble in twenty-four cases.

Cord Bladder.—The breakdown of the tabetic patient's urinary excretory mechanism begins with a gradually developing atony of the bladder, which may fail to attract the patient's attention, and be missed by the examiner in taking the history. It is a not uncommon misconception that dribbling means an empty bladder with relaxed sphincter, rather than an overfilled bladder, as is usually the case. The collection of the urine in an atonic bladder, the back pressure and consequent diminished renal function, may come on so insidiously that, as in one case in our experience, a uremic attack may be the first warning that the excretory mechanism had broken down. The first duty of the physician, therefore, in assuming charge of a tabetic patient, is to ascertain his blood urea content and his phenolsulphonephthalein elimination. The amount of residual urine may be determined under suitable conditions, but in an uninfected and only mildly atonic bladder, there should be some hesitation in assuming even the slight risk of infection inherent in catheterization. The response of the nervous mechanism of the atonic bladder to treatment is probably considerable. In most cases the effect is, however, concealed in part by the additional relief afforded the overdistended and inflamed organ by irrigation and catheterization. In the seventy-three cases studied in this series with the aid of the Urologic Section of the Mayo Clinic, it was found that the improvement depends largely on the grade of involvement when treatment is begun. Mild and moderate degrees of cord bladder show excellent and good results in approximately 70 per cent. of the cases. In severe grades of involvement, good results were secured only in approximately 15 per cent. of the cases. The results for the group as a whole (Chart 6) were good in 32 per cent. and fair in 29 per cent. We have seen a residual urine of 22 ounces (650 c.c.) reduced to one-half ounce (15 c.c.) with practically complete restoration of bladder function in the course of a year of combined systemic and local treatment. It is important to teach the tabetic patient the importance of bladder control, and to have him make a systematic effort to empty the bladder spontaneously at least once each day. Squatting, crouching, stooping and other postures may assist, with the sound of running water, heat over the bladder, evacuation in the hot sitz-bath, etc. Practice may restore much more than is expected at the outset. Too early resort to the catheter, and self-catheterization should be avoided. In very late cases with a high blood urea, gradual emptying of the infected bladder followed by a continuous catheter drainage (night and day) may bring about a slow improvement in renal function and a corresponding gain in the patient. Stab drainage in one case restored a tabetic "wreck" in his sixth decade to the efficiency of his forties. Urologic consultation should be called in doubtful cases.

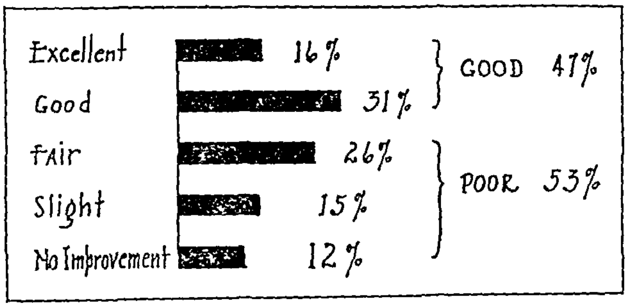

Chart 5.—Clinical response of lightning pains in 124 cases.

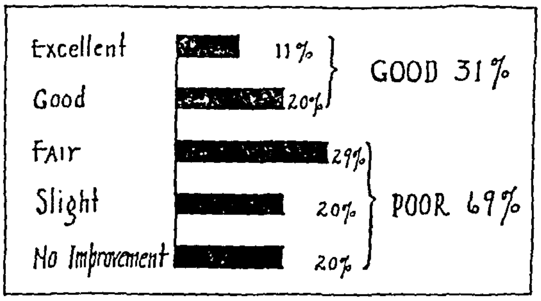

Chart 6.—Clinical response of cord bladder in seventy-three cases.

Gastric Crises.—Of seventeen cases, complete recoveries were secured in only two during prolonged observation (Chart 7). On the other hand, marked amelioration is possible in 24 per cent., and no improvement occurred in 23 per cent. The usual response consists in a reduction of the severity and length of the attacks with or without an increase in intervals between attacks. This degree of improvement may restore a previously incapacitated person to self-support. The combating of the neurosis, the fear and hopelessness that seem to be psychic accompaniments of the condition are often as difficult as any phase of the treatment. The cardinal error of the profession in dealing with gastric crises at the present day is in the use of morphin. If the physician in ordinary practice could be induced never to give a hypodermic injection for abdominal pain without testing the pupils and knee jerks, there would be a worth-while improvement in the outlook of the average patient with gastric crises. The combination of morphinism and gastric crises is as distressing and refractory as anything in medicine. McFarland[7] described the symptomatic relief afforded in our experience by the intrarectal use of chloral and sodium bromid, each 30 grains (2 gm.), in 1 ounce (30 c.c.) of water. If the room is darkened and the buttocks are elevated, relief often follows within a few minutes, and in an hour the patient may fall asleep. Chloral delirium, while a rare complication, must be watched for after repeated doses. The intelligent patient may in some cases be taught to manage his own crises in this fashion. Washing the stomach occasionally shortens an attack, and bizarre devices, such as "stretching" the patient by bending him backward over the end of the bed, are said occasionally to stop an attack. Our experience with procain injection about the splanchnic nerves has not, on the whole, been favorable. While the occasional attack is reduced in severity, the pain relieved, or even occasional aborting of the attack produced, the effect is not invariable, uniform or lasting. The patient under treatment for gastric crises should be systematically encouraged to make up the weight loss, which occurs during attacks, by gorging himself just short of dyspepsia in the intervals. Not a moment should be lost when the vomiting ceases. The most nourishing foods should be taken in abundance, for the general outlook of the case depends to no small degree on the patient's ability to keep ahead of his threatened cachexia until treatment shall have taken effect. In occasional cases in which the crisis has become an almost continuous affair of morning vomiting, feeding through the duodenal tube during the free interval of the day has produced a gain in weight sufficient to turn the tide for the time being. The bringing on of an attack by an arsphenamin injection, and its aborting with epinephrin intramuscularly, are now fairly familiar. Intraspinal treatment may likewise bring on an attack. Tryparsamide, tried in several of our cases, produced what appeared to be temporary remissions in two or three instances, but in the more intractable cases was without effect, either tonic or specific, and seemed even to increase the severity of the attacks.[8]

[7] McFarland, A. R.: Palliative Control of the Gastric Crises of Tabetic Neurosyphilis by the Rectal Administration of Chloral Hydrate and Sodium Bromid, J. A. M. A. 78:786 (March 18) 1922.

Ataxia.—In sixty-three cases, 21 per cent. obtained good results, and 79 per cent. fair or poor results (Chart 8). This low proportion of improvements evidences the late degenerative character of the symptom. So poor a prognosis does not necessarily hold, however, for we have seen ataxic patients who could scarcely "flop" about the office, walk so well in six months that we could not recognize them when they passed us in the corridor. This is especially true of the early cases in young patients who are carefully prepared with mercury and iodid and not given arsphenamin too promptly or in too large doses. The definitely ataxic patient, while he may not always be able to command the facilities of a Fraenkel gymnasium, can be helped a good deal under ordinary circumstances by being taught to substitute his eyesight for his sense of motion and position, and to look at his feet as he walks. This, with a restoration of confidence and some exercises at planting his feet on painted foot-marks, will help him considerably. The psychic factor in ataxia is quite apparent to any considerable experience, and it must be realized that the patient who flounders in one's presence may make a much better showing in a crowded street where he loses his self-consciousness. Patients with marked ataxia should not, in general, be subjected to avoidable spinal punctures, for in occasional cases there seems to be increased difficulty afterward.

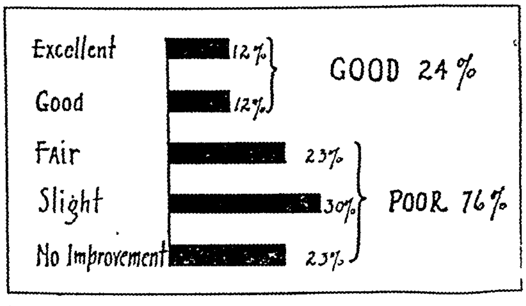

Chart 7.—Clinical response of gastric crises in seventeen cases

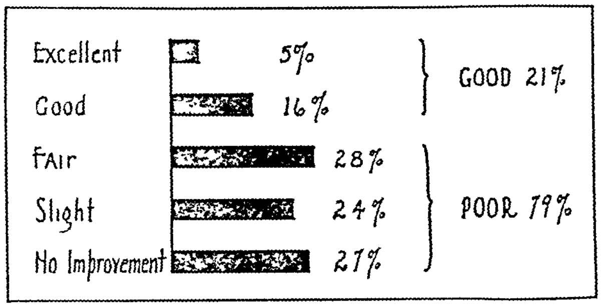

Chart 8.—Clinical response in ataxia in sixty three cases.

Optic Atrophy.—In ten cases of the primary type which fell within the requirements of the series here discussed, we were unable to record a single improvement. Occasionally, in the very earliest cases, it seems possible to arrest the process, but the far more usual rule is a steady progress of the impairment, definitely accelerated at times, we believe, by the use of arsphenamin. We are inclined to depend on mercuric succinimid intramuscularly and iodid by mouth for a long preparation (two months). Patients with beginning primary optic atrophy should be prepared, while they still have vision, for the possibility of losing it, so that they may remain at least partially self-supporting. The invincible optimism that seems to accompany the state, or the euphoria of the paretic, of course, makes this difficult.

The function of individualization in the management of tabes does not consist, as sometimes would seem to be the case, in finding excuses for not treating the patient, but rather in a judicious alinement of all resources, in his behalf. Reduction of serologic findings to normal is a goal to be sought with intelligent persistence. Not the least of the important general measures is a restoration of the patient's confidence in the possibility of a considerable degree of relief and a return to reasonable economic efficiency. Encouragement, quite as much as drugs; rest, but not too much of it; protection from hardship, exposure, worry, infections; and (too often forgotten) study of the family for evidence of conjugal or inherited infection, are vital parts of management.

3800 Chestnut Street—University of Pennsylvania School of Medicine.

[8] No attempt has been made to summarize experience with section of the posterior roots in the treatment of gastric crises (Foerster operation), since opinion and practice as to either technic or value have not crystallized. Our own observations do not warrant conclusions. The procedure at present is one of last resort.

Emergency Fund for Prevention of Disease.—In order to be in position to combat the spread of cholera, yellow fever, smallpox, plague, typhus fever, trachoma, infantile paralysis, Rocky Mountain spotted fever, and influenza, Congress provides an emergency fund of approximately half a million dollars annually for expenditure by the Public Health Service in threatened or actual epidemics.—Kerr, J. W.: *Pub. Health Rep.* **40**:1681 (Aug. 14) 1925.

SIGNIFICANCE OF NORMAL SPINAL FLUID IN CASES OF NEUROSYPHILIS *

PAUL A. O'LEARY, M.D.
AND
MARQUE O. NELSON, M D
Fellow in Dermatology, the Mayo Foundation
ROCHESTER, MINN.

In 1921, Solomon and Klauder[1] reported on the various types of neurosyphilis in which there may be completely negative spinal fluid findings with or without clinical symptoms. Pardee,[2] Fordyce and Rosen,[1] and others have also called attention to this phenomenon. These reports and our own confirmatory observations have established the fact that neurosyphilis may be clinically inactive or progressive in the presence of normal spinal fluid. The fact that the fluid findings reversed to normal as a result of treatment or the patient's own resistance does not seem to have much bearing on the clinical picture. In referring to the normal spinal fluid, we include only those cases that were within normal limits in all four tests on the fluid. A cell count of 7 or more was considered positive.

Table 1 (Group 1).—*Effect of Treatment on the Persistent Symptoms After the Spinal Fluid Became Negative* *

	Much Improvement	Slight Improvement	No Change
Primary optic atrophy	1	0	5
Rectal crises	0	1	0
Trophic ulcers	1	0	2

Paresthesias	2	3	3
Bladder incontinence	5	4	9
Numbness of hands and feet	4	1	7
Ataxia	0	1	2
Hemiplegia	0	2	1
Nervousness	3	0	1
Diplopia	5	1	0
Weakness	6	1	2

* Symptoms given in order of persistence, from above down

Solomon and Klauder called attention to the fact that the vascular types of neurosyphilis are, as a rule, negative in the spinal fluid, and that other types, such as tabes dorsalis, cerebral gumma, cerebral nerve palsy, spastic paraplegia, syphilitic epilepsy and syphilitic psychosis, may often be clinically progressive with negative tests of the spinal fluid.

Serologically negative neurosyphilis has been recognized for several years, but few examples are reported in the literature. It has always been difficult to decide whether antisyphilitic treatment should be continued in such a case, or whether the patient should be permitted to rely entirely on his own resistance mechanism for future protection from the disease. Certain syphilologists do not treat asymptomatic serologically negative but clinically positive neurosyphilis because of the negative reports on the spinal fluid. Others believe that the patient with asymptomatic neurosyphilis, who has had a complete reversal of the spinal fluid as a result of treatment, will not continue to progress clinically.

Only three of the many phases of the disease in which the spinal fluid was negative will be discussed in this paper; they are grouped as follows: (1) clinical evidence of neurosyphilis with negative serologic findings as a result of treatment; (2) clinical signs of neurosyphilis, but negative serologic findings without treatment, and (3) asymptomatic neurosyphilis with favorable reversal of findings in the spinal fluid with treatment. All the patients were observed for a period of at least eighteen months after the fluid became normal; the average period of observation was thirty-two months; the longest was six years. The patients studied had received at least one series of six arsphenamin injections and a corresponding amount of mercury. Paretic patients were not studied.

The three groups were studied with particular reference to the type of neurosyphilis; the symptoms that persisted after the fluid became negative; the influence of continued antisyphilitic treatment on these symptoms; the new symptoms that developed after the spinal fluid had reversed; the improvement or progression in the signs of the disease after the serologic reversal; the contrast between the changes in the spinal fluid and the serum Wassermann reaction; the evidence of the visceral progress of the disease in the presence of the neurologic arrest, and the influence of continued treatment in each group as a whole.

One hundred and thirty-five case records were selected for study from a review of more than 2,000 records of neurosyphilitic patients. No effort was made to estimate the frequency of the serologically negative neurosyphilitic case in the various anatomic types of neurosyphilis, since such an estimate did not appear significant here. The good results in the treatment of neurosyphilis in its early manifestations have been reported by Fordyce,[4] Wile,[5] Stokes and Shaffer,[6] Moore,[7] and others. It is impossible to estimate accurately the total percentage of good results obtained by the various authors. We believe, however, from a review of the literature and our own experience, that complete serologic arrest is obtained in approximately 50 per cent. of all types of neurosyphilis, exclusive of the paretic type, in which adequate treatment is given. In a small percentage of these, there is only partial relief from symptoms, even though the serologic result has been excellent. We are firm advocates of the intensive modern treatment of neurosyphilis when recognized early in its course, and wish to avoid the impression that this report is in any way derogatory to such treatment.

GROUP 1. CLINICAL EVIDENCE OF DISEASE, WITH NEGATIVE SEROLOGIC FINDINGS AS A RESULT OF TREATMENT

In Group 1, there were sixty-one cases in which active symptoms of the disease continued after the spinal fluid became negative. Each patient had at least two neurologic examinations and two spinal fluid tests after the spinal fluid became normal, and was observed for a period of more than eighteen months. We believe that the symptoms and signs persisting after the fluid has become negative are the result of the residue of the degenerating process in the nervous system, and that this "scarring" may produce signs and symptoms as active as the original syphilitic process.

In this group are forty-eight patients with tabes dorsalis, four with parenchymatous neurosyphilis, two with combined sclerosis, one with meningoparenchymatous syphilis, three with parenchymatous vascular syphilis, one with meningovascular-parenchymatous syphilis, and two with an indeterminate type of neurosyphilis. All these patients were in the early or only moderately advanced stages of the disease.

The majority of these patients had thorough antisyphilitic treatment in an effort to reverse the findings in the spinal fluid; fifty-five had treatment classified as "excellent," five as "good," and two as "poor."[8] Certain of the symptoms which were given as the chief complaint at the time of admission to the clinic persisted after the fluid became negative. They are given in the order of frequency (Table 1).

Table 3 (Group 1).—*Changes in the Neurologic Signs After the Fluid Became Normal*

Change in location and degree of hyperesthesia in three, some improvement in one
Further reduction in the deep reflexes in four; became more active in three
Ataxia progressed in two
Pain sense more extensive in six; less marked in one
Temperature sense more extensive in five; less marked in two
Degree of positive Romberg increased in two; lessened in one
Vibration disturbances increased in four; diminished in one
Astereognosis more marked in six; improved in none
Pupil reaction reduced to light in one
A total of twenty cases

An effort was made to determine the new symptoms that developed after the fluid became negative. Changes in the nervous system producing these symptoms were probably present before the findings in the fluid reversed, but they were not complained of by the patient. The symptoms are given in the order of the frequency of their appearance (Table 2).

There were twenty cases in this group that received more than one complete neurologic examination two years after the fluid became negative; in twelve of the cases, definite progress of one or more of the neurologic signs was manifested, while in eight, such progress did not occur (Table 3).

Serum Wassermann Reaction.—A study of the blood Wassermann reaction in this group shows further evidence of the uncertainty of the blood serum Wassermann reaction as a guide to diagnosis or treatment, because in forty-two of the sixty-one cases, the blood Wassermann reaction was negative throughout the period of observation; in nine, the reactions were positive at the onset but reversed to negative under treatment; in six, they were negative to start with, and changed to positive after the first series of treatment and then reverted to negative again (provocative?); while in three, after remaining negative for periods of more than three years, they reversed to positive. In only one case in the group did the reaction remain positive throughout an observation period of four years.

Table 4 (Group 2).—*The Influence of Treatment on Persistent Symptoms*

	Improvement	No Change

[illegible]	3	5
[illegible]	0	2
[illegible]	1	2
[illegible]	1	3

Symptoms are given in order of frequency, from above down

Cardiovascular Syphilis.—Of the thirty-four patients in the group who were specially examined for evidence of cardiovascular syphilitic disease, twenty-seven were normal, two had moderate hypertension; one had arteriosclerosis; one, hypertension; one, endocarditis, and only two had definite syphilitic aortitis that was recognized after treatment had been started. This is quite in contrast with the frequent association of cardiovascular syphilis and active neurosyphilis. Both of these patients were observed over a period of years and showed no progress in the aortic disease. No doubt, if this group came to necropsy, a higher percentage of cardiovascular disease would be demonstrated, but it is significant that so few of them showed definite clinical evidence of heart disease on special cardiovascular examination.

The Somatic Results of Treatment.—Of the patients who were well treated, 24.5 per cent. showed no symptomatic improvement, 37.75 per cent. recovered incompletely and were still incapacitated, and 37.75 per cent. manifested definite symptomatic arrest of the disease as the result of the continuation of treatment after the negative result in the spinal fluid had been obtained.

Table 5 (Group 2).—*Symptoms Appearing During Course of Treatment*

	Cases
Tingling of feet and hands	2
Ataxia	2
[illegible]	2
[illegible]	2
[illegible]	2
[illegible]	1
Cardiac decompensation	1
Ptosis of eyelid	1
Diplopia	1
Dysphagia	1
Convulsions	1
Nervousness	1
Trophic ulcer	1
Progressive changes in pupillary reflexes	1
Headaches	1

GROUP 2. CLINICAL EVIDENCE OF DISEASE, BUT NEGATIVE SEROLOGIC FINDINGS WITHOUT TREATMENT

Group 2 comprises twenty-nine patients who when first seen showed active symptoms, definite clinical evidence of neurosyphilis and a normal spinal fluid without history of previous treatment. Twenty-six of the patients had tabes dorsalis, one had parenchymatous vascular syphilis, one had syphilitic combined sclerosis, and one had juvenile tabes dorsalis.

---

[8] This classification was made for the sake of convenience. "Excellent" indicates that more than eighteen arsphenamin treatments with corresponding amounts of mercury and at least six intraspinal treatments were given. "Good" signifies that between twelve and eighteen arsphenamin treatments with a corresponding amount of mercury and less than five intraspinal treatments were given. All less intensive treatment is classified as "poor."

Treatment was well carried out because of the active symptoms that compelled "excellent" treatment of twenty-five patients, while only three received "good" treatment, and one "poor." An estimate of the effect of continued treatment in the patients' general condition showed that thirteen were definitely benefited, eleven were improved in one or more of the main complaints, and five were not helped (Tables 4 and 5).

Changes in the Neurologic Signs.—In eleven cases, repeated neurologic examinations were made at intervals of more than eighteen months; in five, definite progression in the signs was found, while in six, no change was observed. The most frequently noted improvement in these signs was in the pain and temperature sense in the lower extremities, while the augmented reduction of the deep reflexes was the common progressive sign of retrogression. In two cases, all the signs progressed, while in a few, nystagmus, ptosis of the eyelids and ataxia progressed markedly.

Cardiovascular Syphilis. — There were thirteen patients in this group who had a special cardiovascular examination, of whom only one showed clinical evidence of syphilitic aortitis, nine were completely negative, and one had hypertension, one arteriosclerosis and one endocarditis (nonsyphilitic).

Serum Wassermann Reaction.—There were fifteen of the twenty-nine cases whose blood showed a negative Wassermann reaction at the first examination and throughout the course; in three, the reaction was negative at the start but reversed to positive and back to negative again with continued treatment; in eight, the reaction reversed from positive to negative; while in three the reaction stayed positive throughout the period of observation.

GROUP 3. ASYMPTOMATIC NEUROSYPHILIS WITH FAVORABLE REVERSAL OF THE FINDINGS IN THE SPINAL FLUID UNDER TREATMENT

There were forty-five patients in Group 3. They were observed over a period of more than two years, during which time the spinal fluid and the nervous system were repeatedly examined. Three patients developed lightning pains, and two, girdle pains and paresthesia around the waist, but none developed neurologic signs sufficient to warrant a diagnosis of neurosyphilis. The frequency with which a tendency to neurasthenia appeared was the outstanding characteristic of the group. One patient had previously undergone a special cardiovasular examination for evidence of syphilitic heart disease with completely negative results, fully developed aortitis appearing eighteen months after the fluid and blood had become normal; while another patient who had syphilitic aortitis showed no progress in the disease, as indicated by the findings on three subsequent examinations. We were unable to demonstrate any progress in the visceral syphilis in the patients of this group other than in the aorta.

The Wassermann Reaction of the Serum and Spinal Fluid.—In fifteen cases, a negative Wassermann reaction at the onset of treatment was not altered throughout the course of treatment. Of the remaining thirty with positive reaction in the serum, the blood showed reversal before the spinal fluid in nine; in five, reversal was simultaneous; in thirteen, reversal of the serum reaction followed six or more months after the reversal in the fluid, and in three, it became negative with that of the fluid but later reversed to positive and remained so.

The treatment in this group was classified as "excellent" in thirty-eight, and "good" in seven.

TABLE 6 (Case 3).—*Observations in a Case of Tabes Dorsalis and Charcot Ankle* *

	Cerebrospinal Fluid				Treatment

8/22/22	+++	+	27	023300000000000	(Showed symptoms of paresis)						

* A man, aged 42, had definite signs of tabes dorsalis complicated by a Charcot ankle. The clinical improvement was very marked with the exception of the Charcot ankle, which later necessitated amputation. Evidence of mental degeneration was noted at time of recurrence.

COMMENT

The types of neurosyphilis that have been known to pursue an unfavorable clinical course in the presence of negative tests in the spinal fluid and serum have been mentioned. They are not rare in the syphilologic clinic, as Stokes and DesBrisay[9] showed that 7.5 per cent. of a well treated group were serologically arrested yet symptomatically progressive. Solomon and Klauder[10] have suggested the use of the provoked spinal fluid reactions as a means of determining the activity of the neurosyphilis. We are in accord with them in that we believe a provoked result is from time to time noted in the fluid reactions of patients under treatment for neurosyphilis. It would also seem that this reaction is more the result of the provocative influence than a so-called "Herxheimer reaction."

Grindon[11] and Hazen[12] have suggested that continued treatment may maintain a positive reaction in the blood serum. We have observed a similar phenomenon in the spinal fluid, on a number of occasions, in patients who have received intensive treatment over a period of several years. It will be advisable to observe these patients for some time before endeavoring to draw conclusions from this observation.
